#### Inelastic Aseismic Design of Reinforced Concrete Bridges

Yoshikazu YAMADA Hirokazu IEMURA

Professor Assoc. Prof.
Kyoto University
Kyoto, Japan Kyoto, Japan

As stated in the introductory report by Professor Tassios, it is an essential approach for earthquake resistant design of most structures to produce a structure capable of responding to moderate shaking (more than a few times expected intensity of excitation in its life time) without damage, and capable of resisting to unlikely event of very strong shaking without seriously endangering the occupants. In the first case, it is satisfactory to adopt the "allowable stress" design method for the specified intensity of earthquake motion. However, in the second case, it is neccesary to propose reasonable design methods based on earthquake response properties of structures beyond yielding limit approaching to failure.

#### INELASTIC DESIGN CODES

In the first part of this study, present two inelastic earthquake resistant design codes of reinforced concrete (RC) bridges by Japan Road Association are explained and some problems in application are pointed out. One inelastic design is a static method by which it should be checked whether sectional forces due to 30% increased earthquake loads (130% of the intensity for elastic design) are less than ultimate strength of those forces. The other is a dynamic method with use of equivalent linearization technique. By this method, it should be checked whether ductility factor response due to 30% increased earthquake dynamic loads is less than the allowable ductility factor which is defined as one third of the ultimate ductility of members. In appliction of these two inelastic design methods to RC bridge structures (especially bridge structures), it was found that the second ductility requirement is generally hard to be satisfied even though several problems relating to values of equivalent damping factor and spectral intensity for dynamic response analysis and definition of the allowable ductility factor have been pointed out. Research efforts are needed to answer these problems.

## HYBRID EXPERIMENTS OF EARTHQUAKE RESPONSE

In the second part of this study, results of the newly developed online hybric experiment related to above mentioned problems are described. In the experiment, earthquake response is calculated by a digital computer adopting the real hysteretic restoring force of a RC bending structural element directly measured from a loading actuator. Therefore, accurate estimation of not only earthquake response but also deterioration process of structural properties has become possible. Effects of reinforcement ratio, axial stress, kinds and amount of tie-hoops and strength of concrete to inelastic earthquake response are examined. Process of partitioning of earthquake input energy to kinetic, potential and absorbed energy by hysteresis loops is also investigated as a measure for deterioration of structural properties. From the experiments, it is found that the ductility requirement by the present code is so conservative that new design codes based on earthquake input energy shall be developed.

# INELASTIC ASEISMIC DESIGN OF REINFORCED CONCRETE BRIDGES

DESIGN FORMATS

PRESENT CODES

1) DUCTILITY REQUIREMENTS

 $\mu_{\text{max}} \leq \mu_{\text{a}}$ 

IN THIS RECURREMENT, DUCTILITY FACTOR RESPONSE IS CALCULATED BY AN EQUIVALENT LINEARIZATION TECHNIQUE IT SHOULD BE OFFICKED WHETHER DUCTILITY FACTOR RESPONSE DUE TO 30% INCREASED EARTHOLIANE DYNAMIC LOADS IS LESS THAN THE ALLOWAELE DUCTILITY FACTOR WHICH SHOULD BE DEFINED FROM THE EXPERIMENTS.

2) ULTIMATE STRENGTH REQUIREMENTS

 $M_{max} \leq M_{u}$ 

THIS REQUIREMENT IS A STATIC METHOD BY WHICH IT SHOULD BE CHECKED WHETHER SECTIONAL FORCES DUE TO 30% INCREASED EARTHQUAKE LOADS ARE LESS THAN ULTIMATE STRENGTH OF THOSE SECTIONS.

RECOMMENDED ENERGY REQUIREMENTS

 $E_{total} \le E_a$ 

FROM ON-LINE HYBRID EXPERIMENTS, IT IS VERRIED THAT HYSTERETIC ABSORBED EMERGY IS THE BEST PARAMETER TO REPRESENT DEGREE OF DAMAGE OF RC STRUCTURES HENCE IT IS RECOMMENDED TO OFFICE WHETHER TOTAL ABSORBED HYSTERETIC EMERGY IS LESS THAN THE ALLOWABLE VALUE WHICH SHOULD BE DEFINED FROM THE EXPERIMENTS.
