# Shear Strength of Unwelded Shear Connectors for Composite Beams

# Résistance au cisaillement de connecteurs non soudés pour construction mixte acier-béton

# Scherfestigkeit von ungeschweissten Schubverbindungen für Verbundträger

# Colin K. JOLLY

Lecturer Univ. of Southampton Southampton, UK

Colin Jolly, born 1950, obtained his Civil Engineering Master's degree and Doctorate at Southampton University. For four years he was involved in the design of concrete water-retaining and building structures. His research interests are in cementitious composites, the in-service monitoring of structures, and composite construction.

#### Stuart S.J. MOY

Lecturer Univ. of Southampton Southampton, UK

Stuart Moy, born 1945, obtained his Civil Engineering degree and Doctorate at Nottingham University. He has worked in the aircraft industry and on the design and construction of cooling towers and nuclear pressure vessels. His research interests are in cooling tower analysis and composite construction.

# Ashraf M. EL-SHIHY

Assistant Lecturer Zagazig University Zagazig, Egypt

Ashraf El-Shihy, born 1955, obtained his Civil Engineering degree at Cairo University and his Master's degree at Southampton. He is currently undertaking research in composite construction at Southampton.

# SUMMARY

This paper describes push-out tests to determine the strength of several fixings used to provide the shear connection between composite slabs and composite beams. The research investigates the effect of varying the pattern of the fixings, the type and orientation of the profiled sheeting, the concrete strength and steel beam size.

# RÉSUMÉ

Cet article décrit les essais de type «push-out» effectués en vue de déterminer la résistance de différents moyens de connexion entre les planchers mixtes avec tôle profilée et les poutres métalliques. L'étude traite de l'influence de l'écartement des fixations, du type et du sens porteur de la tôle profilée, de la résistance du béton et de la dimension de la poutre métallique.

### **ZUSAMMENFASSUNG**

In diesem Referat werden «push-out»-Versuche beschrieben, in denen die Tragfähigkeit von mehreren Befestigungsvorrichtungen bestimmt wird, welche die Schubkräfte zwischen Platte und Träger des Verbundelementes übertragen. In der Forschungsarbeit werden die Auswirkungen untersucht, wenn das Muster der Befestigungsvorrichtungen, die Art und Orientierung der im Querschnitt dargestellten Verkleidung, die Festigkeit des Betons und die Dimensionen des Stahlbalkens verändert werden.

#### 1. INTRODUCTION

Composite slabs of profiled steel sheet permanent shuttering and concrete provide for construction of spans up to three or four metres without additional support from beams. On large contracts, or in bridges, where spans in excess of 10 metres can be required, welded shear connectors provide economic composite beams. The aim of this research, into the use of unwelded shear connections, is to bring the economic advantages of composite beam construction to the intermediate span beams which are more common on smaller construction contracts. In addition, the results show the contribution of the unwelded fixings used to locate the profiled steel sheeting during construction to the shear resistance of composite beams with through—deck welded shear connectors.

Unwelded shear connectors have already been used in the construction of some buildings in the U.K., for example self-drilling, self-tapping screws for a hospital in Oxfordshire, and shot-fired fixings for a multi-storey car park and other small buildings in South Wales. In general, each application has had to be justified by beam load tests.

The advantages of using unwelded shear connectors are that it avoids the requirement for expensive three—phase welding equipment and trained operatives on smaller sites, or where only modest beam spans are used.

These methods of fastening are less weather-dependent, and should be attractive in developing countries where skilled staff are at a premium.

#### 2. THE TEST PROGRAMME

#### 2.1 Test variables

This paper describes the results obtained from push—out tests on four proprietary fixings which may be suitable for providing shear connection in composite beams. The push—out tests were based on the standard dimensions quoted in CP117 [1] for concrete cast directly onto the steel beam. The concrete area was increased, when necessary, to coincide with integer multiples of the pitch of the steel decking profiles. The aim was to ascertain the behaviour of the connections under a wide range of likely practical conditions. Consideration was therefore given to the following wide range of variables:

- the number and pattern of the different fixings,
- the type of profiled sheeting (dovetailed and trapezoidal sections),
- orientation of the profiled sheeting,
- type of concrete (normal weight and lightweight aggregate),
- size of the steel beam section.

A summary of the tests is given in table 1. Variations made to each of these parameters will be described in more detail.

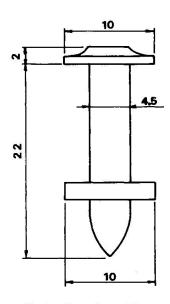

#### 2.2 Fixings

The four types of fixing used as shear connectors in the tests are;

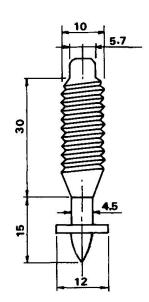

- shot-fired threaded studs,
- shot-fired nails,
- an angle bracket fixed by two shot-fired nails,
- self-drilling, self-tapping screws.

Each of these connections is shown in figure 1.

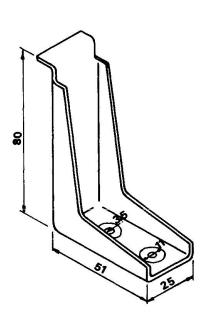

Seven different patterns of connection were used for each of the profile types. The cross-sectional dimensions of each profile influenced the choice of these patterns, which varied from two fixings per face to eight fixings per face in the push-out test (see figure 2).

FIGURE 2. FIXING PATTERNS FOR PUSH-OUT TESTS.

## 2.3 Profiled Steel Sheeting

Two types of profiled steel sheeting were used in the tests: Holorib, produced by Richard Lees Ltd., and CF46 produced by Precision Metal Forming Ltd. The thinnest available gauge of each type of sheeting was used, since shearing or tearing of the sheeting are the only likely effects contributing to any failure mechanism. The results should, if anything, give conservative strengths for the thicker sheeting which is available.

# 2.4 Orientation of the profiled sheeting

Composite slabs are most commonly designed as one-way spanning. The ribs of the sheeting are then orthogonal to the supporting beam which is likely to be designed to act compositely. Some degree of two-way action of the slab is inevitable when there is a trimming beam around the slab. Use of the profiled sheeting was therefore investigated in both orientations.

#### 2.5 Types of concrete

Lightweight aggregate concrete is now common in the U.K. for composite slab/composite beam construction due to the enhanced fire protection provided and the reduced self—weight of members. Three types of concrete were used.

- Normal weight concrete with a target characteristic strength of 40 N/mm<sup>2</sup>. The solids content was in the ratio 1:2.36:4.03 (by weight), with a free water: cement ratio of 0.6. The mix had a 20 mm slump and density of 2350 kg/m<sup>3</sup>.
- Structural lightweight concrete, also with a target strength of 40 N/mm<sup>2</sup>. In this mix 'Lytag' with a maximum size of 10 mm was used as the only coarse aggregate. The solids ratio was 1:2.5:1.59, with a water: cement ratio of 0.75. The density of this mix was 1950 kg/m<sup>3</sup>.
- Lightweight concrete with a target strength of 25 N/mm<sup>2</sup>. Pumice aggregate graded from 15 mm to dust was the sole aggregate in this mix, for which the solids ratio was 1:2.09. A plasticising admixture was added to the water to compensate for the high absorbency of the pumice. The water: cement ratio was 0.65 and the resulting density was 1450 kg/m<sup>3</sup>.

#### 2.6 Size of steel beam

Work-hardening or crystalline phase changes due to heating were considered possible during the installation of the fixings. Any such effects would vary with the thickness of flange to be penetrated. Therefore three different sizes of steel I-beam were used to provide flange thicknesses ranging from 9.7 mm to 12.8 mm. The sections were;

- 305 x 103 UB25,
- 356 x 171 UB45,
- 406 x 178 UB60.

#### 3. RESULTS

# 3.1 Failure modes and maximum shear strengths

There were four main modes of failure.

- Shearing of the connectors, when few connectors were used.
   Shearing of the concrete at the plane connecting the tops of the profiles.
  - Separation of the concrete from the profiled sheeting.
  - Tearing of the profiled sheet under the fixing heads.

When the failure was by shearing of the connectors, the average ultimate shear strengths obtained were 19.25 KN per shot-fired threaded stud, 11.8 KN per shot-fired nail, 20.25 KN per nail used to fix the angle bracket, and 14.38 KN per self-drilling, self-tapping screw.

#### 3.2 The effect of test variables on failure mode and strength

In cases where failure was due to shearing of the fixing itself, less than a 5% reduction in shear strength per fixing was measured when the fixing density was increased. The self-drilling, self-tapping screws were almost twice as ductile as the shot-fired fixings, at equal loads. When failure was by shearing of the fixing or tearing of the sheet, the type of profiled sheeting had little effect. However, when the other failure modes predominated, the CF46 was strongest when orthogonal to the beam, and Holorib strongest when parallel to the beam.

The orientation of the sheeting had little effect when few fixings were used, with failure resulting from shearing of the fixings. When more fixings were used, shearing of the concrete occurred with the Holorib sheeting at shear stresses in excess of 0.92 N/mm<sup>2</sup> (0.59 N/mm<sup>2</sup> in pumice concrete) whereas separation was more likely with the CF46 sheeting at a shear stress above 0.49 N/mm<sup>2</sup> (0.42 N/mm<sup>2</sup> in pumice concrete). Higher shear stresses were required to produce concrete shear or separation failures when longer fixings were used. The longer fixings also produced slightly higher ultimate strengths when the sheeting ribs were parallel to the beam.

Strength results were almost identical when the normal weight and structural lightweight concrete were used. The very light pumice concrete showed signs of aggregate crushing in some tests. The flange thickness of the steel I—beams had no significant effect on the ultimate shear strengths.

#### 4. CONCLUSIONS

Of the four types of fixing tested, only the shot-fired nails showed a tendency to tear through the sheeting. The low shear strength of these nails makes them of little use as independent shear connectors, though they make a useful contribution in conjunction with welded shear studs. The advantages of the self-drilling, self-tapping screws are greater ductility and security of fixing. Ease of fixing is the advantage of the shot-fired stud, but the greatest shear capacity is obtained with the angle bracket and its nail fixings.

Concrete shear failure and separation from the sheeting reduce the potential shear capacity of all these fixings when used independently, but steps could be taken to prevent these failure modes. Density of fixings and sheeting orientation would then have little effect on the shear strength.

Lightweight aggregate concrete should be avoided unless a structural lightweight mix is used, incorporating sand to prevent local crushing. Fire-rating and overall cost currently favour the use of lightweight coarse aggregate. Provided the fixings can penetrate the flange, any steel section can be used

Full-scale beam tests are currently under way to justify the use of the push-out test results in composite beams incorporating the use of unwelded fixings as shear connectors.
