Abstract

Wing segments are developed aiming the efficient moment transfer at the joints of shield lining to maintain necessary lining stiffness in very soft ground where enough passive pressure is not mobilized, and to reduce the cost of joints. In developing wing segments full-scale loading tests have been conducted. The test results show that maintaining the shearing stiffness at the end of wing joint could attain sufficient moment transfer at joints. Unlike ordinary segments, the moment transfer by bolts is not significant and the number and size of bolts could be reduced in the segments.

1. Introduction

In Japan shield tunnels are often constructed in soft ground. Accordingly enough passive pressure is not mobilized and a large bending moment occurs in the lining. For ordinary rectangular segments, lining stiffness is covered by the longitudinal joint positions are not continuous for tunnel axis (hereafter referred to as staggered pattern). To maintain strength of the lining and prevent joint opening are needed, however, heavily reinforced and expensive joints are required.

The authors developed a wing segment that reduces the number of bolts used and decreases the bolt diameter by modifying the shape of the segment pieces. The longitudinal joints have extension part in circumferential direction that equal about half width of the segment, and tenons that we call shearing keys are placed in the joint surface. Wing segment can be attained efficient moment transfer caused by shearing stiffness, and sufficient ring strength and ring stiffness in very soft ground. This paper presents a basic construction of the wing segment and the results of the loading tests conducted with full-scale segments (5300mm external diameter, 1200mm width, 250mm thickness, six pieces).

2. Basic Construction of Wing Segments

2.1 Shape

Figure 1 shows the basic construction of wing segments. The segments are made up of the "main section" and "wing sections." The longitudinal joint surfaces of the segments have shearing keys, so that shear resistance force can be transmitted effectively.

2.2 Mechanism of Bending Moment Transfer

Fig. 1 Basic Construction of Wing Segments

Figure 2 shows the structural transmission mechanism of bending moment in the wing segment joint. The bending moment that works on the joint (M) is divided into that which works on the bolts (Mb) and that which works on the base of the wing section (Mw). Mw is the sum of the bending moment that works on the shearing key $(Ms = Sj \times L)$ and Mb.

M = Mb + Mw

= Mb + (Ms + Mb) = 2Mb + Ms

M : Bending moment that works on the joint.Mb : Bending moment that works on the bolts.

Mw: Bending moment that works on the base of the wing section.

Ms: Bending moment that works on the shearing key (= Sj x L).

Sj : Shearing force that works on the shearing key.

L: Wing length

Ms and Mb resist the bending moment M that works on the joint. Therefore, by placing a higher percentage of the bending moment on the shearing key the burden placed on the bolts can be reduced. In other words, the number of bolts or their diameter can be reduced.

Theoretical analysis was conducted by using a cantilever model as shown in Figure 3. A model was constructed in which both wing sections face each other and are joined by rotation springs and shearing springs.

The cross section of a single subway tunnel was used for the analysis. The relations between the wing length and the bending moment percentage on the bolt, the base of the wing section and the shearing key and between the wing length and equivalent rotation stiffness that converted ordinary joint were calculated. The results of the analysis are shown in Figure 4. The bending moment percentages on the each section are shown below.

Fig. 2 Mechanism of Bending Moment Transfer by Shearing Force

Fig. 3 Cantilever Model

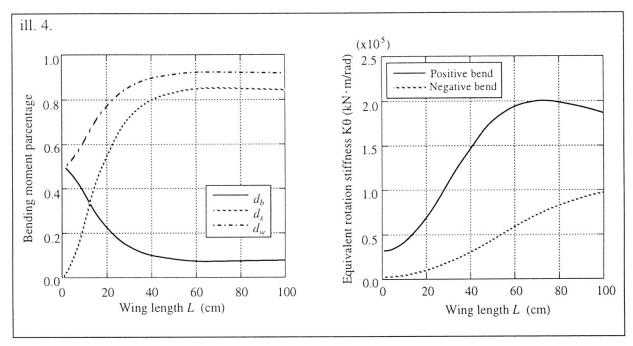

Fig. 4 Wing Length (L) Sensitivity Analysis

db = Mb/M

dw = Mw/M

ds = Ms/M

db : Bending moment percentage on the bolts.

dw : Bending moment percentage on wing section base.ds : Bending moment percentage on the shearing key.

Longer wing sections are better to reduce the burden on the bolts. The analysis showed that the bending moment percentages and equivalent rotation stiffness became changeless when the wing length exceeded 60 centimeters. Therefore, the wing length in the full size segment load presence tests was set at 60 centimeters.

3. Loading Tests Using Full-Scale Segments

The aim of developing wing segments was to attain strength and stiffness equal to or higher than staggered pattern rectangular segments even if wing segments' longitudinal joint positions were continuous for tunnel axis (hereafter referred to as inline pattern). A series of the loading tests using full-scale segments was carried out in order to investigate this. Figure 5 shows the section items for the test piece. The materials used are shown in Table 1.

Fig. 5 Cross Sections of the Test Piece

3.1 Shearing Key Shearing Test

3.1.1 Purpose of the test

To obtain the shearing spring constant and confirm shearing strength of the shearing key on the joint surface.

3.1.2 Testing Method

Figure 6 shows an outline of the testing method. Tests were conducted on the loading conditions that occurred positive bending moment (Case 1) and negative bending moment (Case 2) at the joint. Axial force was set at 441 kN per segment width and 221 kN per longitudinal joint surface to comply with the joint bending test and ring loading test to be described later.

3.1.3 Test Results

1) Shearing strength Table 2 shows the test results. Because compression caused cracks early in Case 2, the collapse load was smaller than for Case 1. However, it was found that the shearing key had sufficient shearing strength because the collapse load is greater

than the design ultimate load,.

2) Shearing stiffness

Figure 7 shows the relations between presence load and shearing deformation. The design values in the figure do not take friction resistance caused by axial force into consideration. Although shearing cracks resulted after the allowable load was exceeded, it can be seen that there are no major changes in shearing stiffness even after the cracks appear. If the shearing stiffness of wing segments are overestimated, the bolts will be underestimated and safety problems will develop. The actual shearing stiffness measured was larger than shearing spring constant design values calculated after considering the stiffness of the concrete and the shear reinforcement. This showed that the design value of the shearing spring constant was safe value.

| Material | Strength properties / Units: N/mm ² | |
|---------------|---|---|
| Concrete | Standard design strength Allowable compressive stress Allowable shearing stress | $\sigma_{ck} = 48$ $\sigma_{ca} = 17$ $\tau_{ca} = 0.74$ |
| Reinforcement | Yield stress Allowable compressive stress Allowable tensile stress | $\sigma_{sy} = 345$ $\sigma_{sa} = 200$ $\sigma_{sa} = 200$ |
| Bolts | Yield stress Allowable tensile stress | $\sigma_{sy} = 940$ $\sigma_{sa} = 300$ |

Table 1 Materials

Fig. 6 Shearing Test Outline

| | | Case 1 | Case 2 |
|------------------|------------------------------------|--------|--------|
| Design values | Allowable load Pa (kN) | 263 | 257 |
| | Final load Pru (kN) | 555 | 512 |
| Test Col | Collapse load P _u (kN) | 842 | 669 |
| values | Safety factor F_s (= P_u/P_a) | 3.21 | 2.61 |

Table 2 Shearing Test Results

Fig. 7 Relations Between Load and Shearing Distortion

3.2 Joint Bending Test

3.2.1 Purpose of the test

To confirm the mechanism of bending moment transfer by the shearing key, and to verify the strength and stiffness of the joint.

3.2.2 Testing Method

Figure 8 shows an outline of the testing method. The load was applied so that the ratio of the bending moment and the axial force was constant until the allowable bending moment. After the allowable bending moment was exceeded, the load was applied so that the axial force remained constant and the bending moment increased. The section forces at the allowable bending moment were set at 368 kN/m for the axial force and 90.7 kNm/m for the bending moment to comply with the final proof stress confirmed through the ring load test.

3.2.3 Test Results

Table 3 shows the test results. The bending moment at collapse was about the same as the design final bending moment. This is believed to be the result of sufficient transmission of the bending moment by the shearing key (shearing resistance (S) x Wing length (L)).

3.3 Ring Loading Test

3.3.1 Purpose of the test

To investigate the strength and deformation properties of the wing segment ring under the axial force.

3.3.2 Testing Method

Figure 9 shows an outline of the testing method. The load was applied so that the ratio of the bending moment and the axis force were constant until the allowable bending moment. Bending moment was applied by placing concentrated loads (Pv and Ph) on the vertical and horizontal directions of the segment. Part-1, 3 were placed on the ring so that the maximum positive bending moment worked on the

Fig. 8 Joint Bending Test Outline

Table 3 Joint Bending Test Results

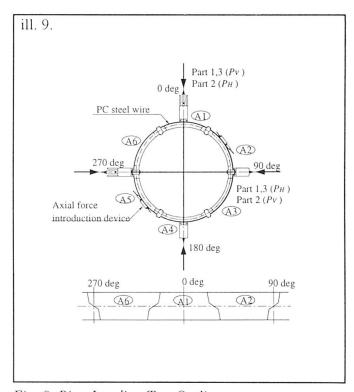

Fig. 9 Ring Loading Test Outline

main section and the maximum negative bending moment worked on the wing sections. Part-2 was placed opposite to Part-1, 3. In the test concentrated loads (Pv and Ph) were introduced proportionately until the design bending moment, but in the final load condition test Ph was set at 0.

3.3.3 Test Results

Figure 10 shows the relations between the load and convergence of the segment ring in Case 3. The specifications of the bolts in the wing segment were smaller than those for conventional bolts. At the allowable bending moment level the ring stiffness was equivalent to or greater than that of the rectangular segment staggered pattern ring calculations in the structural analysis. This shows that the bending moment is transmitted effectively by the shearing keys, and that stiffness has been improved. Also the bending moment distribution in the main section of the segment calculated from the strain measurements on the steel reinforcements is equivalent to the distribution in uniform stiffness rings. Therefore, it was confirmed that wing segments can be designed as uniform stiffness rings ignoring the joint.

Table 4 shows a summary of the final proof stress results. The bending moment at the end of tests was higher than the design final bending moment of rectangular segment staggered pattern rings. This confirms that wing segments can provide sufficient proof stress even inline pattern construction. In each test case bending collapse occurred at the position where the maximum positive bending moment was occurred.

Fig. 10 Relations Between Vertical Loads and Vertical Convergence

| | | Part 1 | Part 2 | Part 3 |
|-----------------------|--------------------------------|-----------------|--------|-----------------|
| Maximum positive bend | | Main section | Joint | Main section |
| Design | M_a (kNm/m) | 110 | 90.7 | 110 |
| values | M_{ru} (kNm/m) | 200 | 178 | 200 |
| Test | $M_{_H}$ (kNm/m) | 209 | 212 | 243 |
| values | Safety factor $F_x (=M_u/M_g)$ | 1.90 | 2.34 | 2.22 |

Table 4 Ring Loading Test Results

4. Conclusions

The conclusions that resulted from the full size segment loading tests were as follows:

- 1) The wing segment feature of transmitting bending moment with shearing stiffness was confirmed, and it was verified that the number of bolts or their diameter can be reduced.
- 2) It was verified that ring proof stress and ring stiffness equal to or greater than that for rectangular segment staggered pattern rings could be achieved with inline pattern construction using fewer bolts or bolts with smaller specifications.
- 3) In joint bending tests where axial force was introduced, joint behavior similar to that in the ring loading test was confirmed. Therefore, it was confirmed that this simple test could sufficiently replace the ring loading tests.
