## Universal octonary diagonal forms over some real quadratic fields

Byeong Moon Kim

**Abstract.** In this paper, we will prove there are infinitely many integers  $n$  such that  $n^2 - 1$  is square-free and  $\mathbb{Q}(\sqrt{n^2 - 1})$  admits universal octonary diagonal quadratic forms.

**Mathematics Subject Classification (2000).** Primary 11E12, Secondary 11E20.

**Keywords.** Universal quadratic forms, real quadratic fields.

### 1. Introduction

A universal integral form over totally real number field  $K$  is a positive definite quadratic form over the ring of integers of  $K$  which represents all the totally positive integers of  $K$ . For example, the sum of four squares is universal integral over  $\mathbb{Q}$ . In 1917, Ramanujan [8] found there are exactly 54 universal positive diagonal integral quadratic forms over  $\mathbb{Q}$ . More concretely, he showed there are 54 diagonal quaternary quadratic forms  $f(x, y, z, w) = ax^2 + by^2 + cz^2 + dw^2$  such that  $a, b, c, d \in \mathbb{Z}^+$  and the equation  $f = n$  is solvable for all  $n \in \mathbb{Z}^+$ . In 1947, M. Willerding [10] proved there are exactly 178 classic universal integral forms. More concretely, she showed there are 178 quaternary quadratic forms  $f(x, y, z, w)$  up to equivalence such that  $f$  is positive definite integral quadratic form, the coefficients of cross terms of  $f$  are always even and the equation  $f = n$  is solvable for all  $n \in \mathbb{Z}^+$ . On the other hand, the study of positive universal quadratic integral forms over totally real number fields was initiated by F. Götzky [3]. In 1928, he proved that the sum of four squares is universal over  $\mathbb{Q}(\sqrt{5})$ . H. Maass [6] improved this result. In 1941, he proved the sum of three squares is positive universal over  $\mathbb{Q}(\sqrt{5})$ . Four years later, Siegel [9] proved  $\mathbb{Q}(\sqrt{5})$  is the only totally real number field, other than  $\mathbb{Q}$ , over which every (totally) positive integer is a sum of squares. In other words, he showed if a totally real number field  $K$  is different from  $\mathbb{Q}$  and  $\mathbb{Q}(\sqrt{5})$ , there is a totally positive algebraic integer  $\alpha$  of  $K$  which cannot be represented by the sum of any number of squares. For example, if  $K = \mathbb{Q}(\sqrt{2})$ ,  $\alpha = 2 + \sqrt{2}$ . In 1996, W. K. Chan, M.-H. Kim and S. Raghavan [1]

classified all (totally) positive universal integral ternary lattices over real quadratic fields. Only  $\mathbb{Q}(\sqrt{2})$ ,  $\mathbb{Q}(\sqrt{3})$  and  $\mathbb{Q}(\sqrt{5})$  admit universal integral ternary lattices and total number of universal integral ternary lattices over real quadratic fields is 11. Recently, the author [5] proved there are only finitely many real quadratic fields which admit universal integral septenary diagonal forms. The content of this paper is to prove if  $n^2 - 1$  is square-free, there are universal octonary diagonal forms over  $\mathbb{Q}(\sqrt{n^2 - 1})$ . So we can prove there are infinitely many real quadratic fields which admit universal integral octonary diagonal forms. Obviously 8 is the minimal rank with this property.

## 2. Main Theorem

Throughout this chapter, we let  $m = n^2 - 1$  be a positive square free integer,  $K = \mathbb{Q}(\sqrt{m})$  and  $\mathcal{O}_K$  be the ring of algebraic integers of  $K$ . Note that  $\epsilon = n + \sqrt{m}$  is the fundamental unit of  $\mathcal{O}_K$  and is totally positive.

**Theorem 1.** *The octonary diagonal form  $x_1^2 + x_2^2 + x_3^2 + x_4^2 + \epsilon x_5^2 + \epsilon x_6^2 + \epsilon x_7^2 + \epsilon x_8^2$  is universal over  $\mathcal{O}_K$ .*

This Theorem is a consequence of following Lemmas.

**Lemma 1.** *Let  $1 \leq b < 2n$ .  $\alpha = a + b\sqrt{m}$  is totally positive algebraic integer in  $K$  if and only if  $nb \leq a$ .*

*Proof.* As  $nb + b\sqrt{m} = b(n + \sqrt{m})$  is totally positive, the necessity is trivial. For the sufficiency, it suffices to prove  $nb - 1 - (b\sqrt{m}) < 0$ . This follows from

$$\begin{aligned} (nb - 1)^2 - (b\sqrt{m})^2 &= n^2b^2 - 2nb + 1 - b^2(n^2 - 1) \\ &= (b - n)^2 - n^2 + 1 \leq (n - 1)^2 - n^2 + 1 < 0. \end{aligned}$$

□

**Lemma 2.** *If  $\alpha \in \mathcal{O}_K^+$ ,  $\alpha$  belongs to*

$$S = \{a_0\epsilon^k + a_1\epsilon^{k+1} + \dots + a_l\epsilon^{k+l} \mid k, l \in \mathbb{Z}, a_0, a_1, \dots, a_l \in \mathbb{N}\}.$$

*Proof.* Suppose  $\alpha = a + b\sqrt{m} \notin S$ . We may assume that  $b > 0$  and  $\text{tr}_{K/\mathbb{Q}}(\alpha) \leq \text{tr}_{K/\mathbb{Q}}(\beta)$  for all elements  $\beta \notin S$ . Then, by Lemma 1, we have  $b \geq 2n$ . Since

$$bn - 1 + b\sqrt{m} = \epsilon^2 + (b - 2n)\epsilon \in S,$$

we also have  $a \leq bn - 1$ . Then,

$$\alpha\epsilon^{-1} = (a + b\sqrt{m})(n - \sqrt{m}) = an - bm + (bn - a)\sqrt{m}.$$

So

$$\begin{aligned} \text{tr}_{K/\mathbb{Q}}(\alpha\epsilon^{-1}) &= 2(an - bm) \leq 2(n(bn - 1) - b(n^2 - 1)) \\ &= 2(b - n) < 2a = \text{tr}_{K/\mathbb{Q}}(\alpha). \end{aligned}$$

So  $\alpha\epsilon^{-1} \in S$ . Thus  $\alpha \in S$ . Contradiction.  $\square$

**Lemma 3.** For  $l \geq 2$ ,  $\epsilon^l = -1 + b_1\epsilon + b_2\epsilon^2 + \dots + b_{l-1}\epsilon^{l-1}$  where  $b_1 \geq 2n - 1$  and  $b_2, \dots, b_{l-1} \geq 2n - 2$ .

*Proof.* We use induction on  $l$ . As  $\epsilon^2 = 2n\epsilon - 1$ , the assertion holds for  $l = 2$ . If this Lemma is true for  $l = s \geq 2$ ,

$$\begin{aligned} \epsilon^{s+1} &= \epsilon\epsilon^s = \epsilon(-1 + b_1\epsilon + b_2\epsilon^2 + \dots + b_{s-1}\epsilon^{s-1}) \\ &= -\epsilon + \epsilon^2 + (b_1 - 1)\epsilon^2 + b_2\epsilon^2 + \dots + b_{s-1}\epsilon^s \\ &= -1 + (2n - 1)\epsilon + (b_1 - 1)\epsilon^2 + b_2\epsilon^2 + \dots + b_{s-1}\epsilon^s. \end{aligned}$$

This proves the Lemma.  $\square$

**Lemma 4.** If  $\alpha \in \mathcal{O}_K^+$ ,  $\alpha = p\epsilon^k + q\epsilon^{k+1}$  for some  $p, q \in \mathbb{N}$  and  $k \in \mathbb{Z}$ .

*Proof.* By Lemma 2,  $\alpha = a_k\epsilon^k + \dots + a_{k+l}\epsilon^{k+l}$  with  $a_k, \dots, a_{k+l} \geq 0$ .

If  $l \geq 2$  and  $a_{k+l} \leq a_k$ ,

$$\begin{aligned} \alpha &= a_k\epsilon^k + \dots + a_{k+l-1}\epsilon^{k+l-1} + a_{k+l}\epsilon^k(-1 + b_1\epsilon + \dots + b_{l-1}\epsilon^{l-1}) \\ &= (a_k - a_{k+l})\epsilon^k + (a_{k+1} + a_{k+l}b_1)\epsilon^{k+1} + \dots + (a_{k+l-1} + a_{k+l}b_{l-1})\epsilon^{k+l-1}. \end{aligned}$$

If  $l \geq 2$  and  $a_{k+l} \geq a_k$ ,

$$\begin{aligned} \alpha &= a_k\epsilon^k + \dots + a_{k+l-1}\epsilon^{k+l-1} + (a_{k+l} - a_k)\epsilon^{k+l} + a_k\epsilon^k(-1 + b_1\epsilon + \dots + b_{l-1}\epsilon^{l-1}) \\ &= (a_k + a_{k+l}b_1)\epsilon^{k+1} + \dots + (a_k + a_{k+l}b_{l-1})\epsilon^{k+l-1} + (a_{k+l} - a_k)\epsilon^{k+l}. \end{aligned}$$

Repeating the same process, we can obtain the desired expression of  $\alpha$ .  $\square$

*Proof of Theorem 1.* If  $\alpha \in \mathcal{O}_K^+$ , by Lemma 4,  $\alpha = a\epsilon^k + b\epsilon^{k+1}$  for some  $a, b \in \mathbb{N}$  and  $k \in \mathbb{Z}$ . If  $k$  is even, by Lagrange's four square theorem,  $a\epsilon^k$  is represented by  $x_1^2 + x_2^2 + x_3^2 + x_4^2$  and  $b\epsilon^{k+1}$  is represented by  $\epsilon x_5^2 + \epsilon x_6^2 + \epsilon x_7^2 + \epsilon x_8^2$ . So  $f$  represents  $\alpha$ . Similarly  $f$  represents  $\alpha$  for odd  $k$ . Thus  $f$  is universal integral over  $K$ .  $\square$

**Lemma 5.** *There are infinitely many square free integers of the form  $n^2 - 1$ .*

*Proof.* If  $n$  is even,  $n^2 - 1$  is square free if and only if both  $n + 1$  and  $n - 1$  are square free. It is known that [4] the number of positive square free integers which do not exceed  $x$  is  $\frac{6x}{\pi^2} + O(\sqrt{x})$ . So the number of positive integer  $n$  such that  $n \leq x$  and both  $n + 1$  and  $n - 1$  are square free is larger than

$$\left(\frac{6x}{\pi^2} + O(\sqrt{x})\right) + \left(\frac{6x}{\pi^2} + O(\sqrt{x})\right) - x = \frac{12 - \pi^2}{\pi^2}x + O(\sqrt{x}).$$

Since  $\frac{12 - \pi^2}{\pi^2} > 0$ , there are infinitely many  $n$  such that  $n \leq x$  and  $n^2 - 1$  is square free.  $\square$

**Theorem 2.** *There are infinitely many real quadratic fields that admit octonary universal forms.*

*Proof.* This is an immediate consequence of Theorem 1 and Lemma 5.  $\square$
