Homotopy classes of total foliations

Masayuki Asaoka, Emmanuel Dufraine and Takeo Noda*

Abstract. On every compact and orientable three-manifold we construct total foliations (three codimension-one foliations that are transverse at every point). This construction can be performed on any homotopy class of plane fields with vanishing Euler class.

As a corollary we obtain similar results on bi-contact structures.

Mathematics Subject Classification (2010). 57R30.

Keywords. Foliations, bi-contact structures.

1. Introduction

1.1. Main results. Let M be an oriented closed three-dimensional manifold. We call a triple $(\xi^i)_{i=1}^3$ of smooth transversely oriented plane fields on M a total plane field if $\bigcap_{i=1}^3 \xi^i(p) = \{0\}$ for any p in M. If each ξ^i is integrable, it is called a total foliation. We say two total plane fields are homotopic if they are connected by a continuous path in the space of smooth oriented total plane fields.

A celebrated theorem due to Wood [16] showed that any plane field on a closed three-dimensional manifold can be continuously deformed into a foliation *in its homotopy class*. In other words, there is no homotopical obstruction to the integrability for the three-dimensional case. The main subject of this paper is to solve the analogous problem for total foliations. That is,

Theorem 1.1. Any total plane field on a closed three-dimensional manifold is homotopic to a total foliation.

In other words, there is no homotopical obstruction to the integrability for total plane fields.

Let us remark that three-dimensional closed manifolds have their Euler characteristic equal to zero, which implies the existence of transversely oriented plane

fields. Similarly, three-dimensional closed manifolds have vanishing second Stiefel—Whitney class, which implies the existence of total plane fields.

Hardorp [10], showed that any three-dimensional oriented closed manifold admits a total foliation. However, his construction does not allow to keep track of the homotopy class of the constructed object.

Tamura and Sato [15], gave examples of foliations on three-dimensional manifold which admit a transverse plane field but no transverse foliation. It implies that there exists an obstruction to deform a total plane field into a total foliation *if we fix one of the plane fields as a given foliation*.

Mitsumatsu [13], Problem 5.2.7, asked which homotopy classes of plane fields can be realized as a transverse pair of codimension-one foliations. His question is important from the viewpoint of bi-contact structures, which we consider in the next paragraph. The theory of characteristic classes tells that a plane field is contained in a total plane field if and only if its Euler class vanishes. Theorem 1.1 answers Mitsumatsu's question immediately.

Corollary 1.2. An oriented plane field on an oriented closed three-dimensional manifold is homotopic to a foliation which is contained in a total foliation if and only if its Euler class vanishes.

We call a pair of mutually transverse positive and negative contact structures a *bi-contact structure*. Mitsumatsu [12], and Eliashberg and Thurston [7] showed that bi-contact structures naturally correspond to a *projectively Anosov flow*, which exhibits partially-hyperbolic behavior on the whole manifold.

In relation with the question above, Mitsumatsu asked which homotopy class of plane field can be realized by contact structures in a bi-contact structure. In Theorem 2.4.1 of [7], Eliashberg and Thurston showed that any foliation except the product foliation $\{S^2 \times \{p\}\}_{p \in S^1}$ on $S^2 \times S^1$ can be C^0 -approximated by positive or negative contact structures. It is easy to see that any mutually transverse plane fields are homotopic to each other and that the product foliation on $S^2 \times S^1$ does not admit a transverse foliation. Hence, the following is an immediate consequence of Eliashberg–Thurston's theorem and Corollary 1.2.

Corollary 1.3. On any oriented closed three-dimensional manifold, any oriented plane field with Euler class zero is homotopic to positive and negative contact structures which form a bi-contact structure.

Among the realization problems of bi-contact structures, the following is quite natural.

Question 1.4. Let ξ and η be positive and negative contact structures on an oriented three-dimensional manifold M. Suppose that they are contained in the same homo-

topy class of plane fields with vanishing Euler class. Can we isotope ξ and η so that (ξ, η) is a bi-contact structure?

We give an answer for overtwisted contact structures.

Theorem 1.5. Let ξ and η be positive and negative overtwisted contact structures contained in the same homotopy class of plane fields and with Euler class zero. Then, we can isotope ξ and η so that (ξ, η) is a bi-contact structure.

The answer for tight contact structures is still unknown.

1.2. Outline of proofs. The proof of Theorem 1.1 is obtained after performing a sequence of surgeries and gluings along so-called \mathcal{R} -components, which are solid tori equipped with a 'simple' total foliation.

Section 2 is devoted to the study of the effect of a surgery on the homotopy class of a total foliation. In Subsection 2.1, we review two invariants of total plane fields that determine its homotopy class completely—the *spin structure* and the *difference of Hopf degree*. In Subsection 2.2, we define \mathcal{R} -components of total foliations and gluing of two total foliations along the boundaries of \mathcal{R} -components. In Subsections 2.3 and 2.4, we define a surgery of a total foliation along an \mathcal{R} -component and give a surgery formula.

Section 3 is the main part of our construction of a total foliation in any given homotopy class. It is done by a modification of Hardorp's construction in [10]. The main new feature in our construction is a control of the framing of $\mathcal R$ components by insertion of 'plugs' (Lemma 3.22). Insertion of plugs of another type also enables us to control the difference of Hopf degree (Lemma 3.24). In order to obtain such plugs, we need to construct total foliations on the three-dimensional sphere S^3 such that the cores of $\mathcal R$ -components form special framed links. Hardorp's construction is insufficient to our purpose since the framing is a very large positive number and it is difficult to control. In the first step of our construction, there are two differences from his construction:

- (1) our construction is performed on a non-trivial \mathbb{T}^2 -bundle over the circle while Hardorp's was on \mathbb{T}^3 ;
- (2) foliations in our \mathcal{R} -components may rotate several times in some sense while they did not in Hardorp's.

These differences leads to a simpler construction in the succeeding steps: we can avoid dealing with a finite covering of a total foliation on the Poincaré sphere and with a branched double covering along the unknot. As a consequence, we can obtain an explicit description of the framings of \mathcal{R} -components in terms of diagrams of braids, see Proposition 3.21.

In Subsection 3.2, we give a construction of total foliations on $\mathbb{T}^2 \times [0,1]$. In Subsection 3.4, we describe the framings of \mathcal{R} -components of a total foliation that

is given by gluing two boundary components of $\mathbb{T}^2 \times [0,1]$. In Subsection 3.5, we control the framings of \mathcal{R} -components and show a generalized version of Hardorp's theorem, *i.e.*, the existence of a total foliation with any given spin structure. The control is done by successive replacements of an \mathcal{R} -component with a totally foliated solid torus which contains a twisted \mathcal{R} -component ('insertion of plugs'). In Subsection 3.6, we give a control of the Hopf degree. In fact, we construct a total foliation on S^3 that admits unknotted \mathcal{R} -components with (+1)- and (-1)-framings and that has the required difference of Hopf degree with the positive total Reeb foliation. By gluing it with a total foliation that has the required spin structure, we obtain a total foliation in any given homotopy class of total plane fields.

Section 4 is devoted to the proof of Corollary 1.3. We show that if a total foliation admits an unknotted \mathcal{R} -component with (+1)-framing then any positive contact structure that is sufficiently close to one of the foliations violates the Thurston-Bennequin inequality and therefore is overtwisted. Once it is shown, the corollary is an easy consequence of Eliashberg's classification of overtwisted contact structures in [6].

1.3. Acknowledgements. This paper was prepared while the first and third authors stayed at Unité de Mathématiques Pures et Appliquées, École Normale Supérieure de Lyon and it started when the second author was at Institut Fourier, Grenoble. They thank the members of those institutions, especially Professor Étienne Ghys for his warm hospitality. The authors are also grateful to an anonymous referee for many suggestions to improve the readability of the paper.

2. Gluing and surgery of total foliations

2.1. Homotopy classes of plane fields. In the rest of the paper, all manifolds and foliations are of class C^{∞} and all plane fields and foliations are transversely oriented.

Fix an n-dimensional manifold X equipped with a Riemannian metric. Let Fr(X) be the set of orthonormal frames of TX. It admits a natural topology as a subset of the set of n-tuples of vector fields on X.

When M is a three-dimensional manifold, by taking the unit normal vectors of a total plane field, and by applying the Gram-Schmidt orthogonalization to it, we can define a continuous map from the set of total plane fields to Fr(M). It is easy to see that it induces a bijection between homotopy classes. So, we consider Fr(M) instead of the set of total plane fields in this subsection.

First, we review some basic facts on spin structures. We denote by SO(n) the group of special orthogonal matrices of size n. Let X be an n-dimensional manifold with $n \geq 3$. We fix a triangulation of X and let X_i be the i-skeleton of X for $0 \leq i \leq n$. By $Fr(X_i)$, we denote the set of orthonormal frames of $TX|_{X_i}$. A spin structure is a homotopy class of $Fr(X_1)$ of which each representative can be extended to an element of $Fr(X_2)$. In particular, a frame \check{e} in Fr(X) induces a spin structure on

X in a natural way. We call it the *spin structure* given by the frame \check{e} . Our definition is different from the standard one that is given by a double covering of a natural principal SO(n)-bundle, but it is known they are equivalent if $n \ge 3$, see [11].

A manifold X equipped with spin structure s is called a *spin manifold*. If X has a boundary ∂X , then s induces a spin structure s' on ∂X . We call the spin manifold $(\partial X, s')$ the *spin boundary* of (X, s).

Now, we focus our attention on spin structures on three or four-dimensional manifolds. We call a four-dimensional manifold X a 2-handlebody if it is obtained by attaching four-dimensional 2-handles to the 4-ball B^4 along a framed link L in $S^3 = \partial B^4$. We say a 2-handlebody X is even if the framing of each component of L is even. See the first paragraph of Subsection 2.3 for the definition of framing of knots.

Proposition 2.1. Any even 2-handlebody admits a unique spin structure. Any closed spin three-dimensional manifold is a spin boundary of a spin 2-handlebody.

Proof. See Section 5.6 and 5.7 of [8].

Let M be a three-dimensional closed manifold. We denote by C(M, SO(3)) the set of continuous maps from M to SO(3). The space Fr(M) of frames admits a natural action of C(M, SO(3)) given by $(\check{e} \cdot F)(p) = (e^i(p) \cdot F(p))_{i=1}^3$ for $\check{e} = (e^i)_{i=1}^3$ and $F \in C(M, SO(3))$. We define a map $\Phi \colon Fr(M) \times Fr(M) \to C(M, SO(3))$ by $\check{e} = \check{e}_0 \cdot \Phi(\check{e}, \check{e}_0)$ for $(\check{e}, \check{e}_0) \in Fr(M)^2$. It is easy to check that $\Phi(\cdot, \check{e}_0)$ is a bijective map between Fr(M) and C(M, SO(3)).

We denote the field $\mathbb{Z}/2\mathbb{Z}$ by \mathbb{Z}_2 . Recall the fundamental group $\pi_1(SO(n))$ of SO(n) is isomorphic to \mathbb{Z}_2 if $n \geq 3$. Let Spin(n) be the universal covering group of SO(n).

Definition 2.2. For $\check{e}, \check{e_0} \in \operatorname{Fr}(M)$, we define $s(\check{e}, \check{e_0}) \in H^1(M, \mathbb{Z}_2)$ by

$$s(\check{e},\check{e_0})([\gamma]_{H_1}) = [\Phi(\check{e},\check{e_0}) \circ \gamma]_{\pi_1} \in \pi_1(SO(3)) \simeq \mathbb{Z}_2$$

for any continuous loop γ in M. We call the above cohomology class the difference of spin structures of \check{e} and \check{e}_0 .

It is easy to see that $s(\check{e}, \check{e_0})$ is well-defined and is determined by the homotopy classes of \check{e} and \check{e}_0 . We can see that $s(\check{e}, \check{e}_0) = 0$ if and only if the restrictions of \check{e} and \check{e}_0 to a fixed 1-skeleton are homotopic. In particular, $s(\check{e}, \check{e}_0) = 0$ if and only if two frames \check{e} and \check{e}_0 give the same spin structure.

Lemma 2.3. If two given frames $\check{e}, \check{e}_0 \in \operatorname{Fr}(M)$ satisfy $s(\check{e}, \check{e}_0) = 0$, then the map $\Phi(\check{e}, \check{e}_0)$ admits a lift $\widetilde{\Phi}(\check{e}, \check{e}_0) : M \to \operatorname{Spin}(3)$.

Proof. The map $\Phi(\check{e}, \check{e}_0)$ induces a trivial map between the fundamental groups. Hence, it admits a lift to Spin(3).

Definition 2.4. When two frames \check{e} and \check{e}_0 of M give the same spin structure, we define the difference of Hopf degree $H(\check{e}, \check{e}_0)$ by the mapping degree of $\widetilde{\Phi}(\check{e}, \check{e}_0)$.

Remark that $H((e^i)_{i=1}^3, (e_0^i)_{i=1}^3)$ coincides with the difference of Hopf degree of non-singular vector fields e^i and e_0^i for any i=1,2,3, which is defined in [5]. It is easy to see that the formulae

$$H(\check{e}_2, \check{e}_1) = H(-\check{e}_1, -\check{e}_2) = -H(\check{e}_1, \check{e}_2),$$
 (1)

$$H(\check{e}_1, \check{e}_3) = H(\check{e}_1, \check{e}_2) + H(\check{e}_2, \check{e}_3)$$
 (2)

hold if \check{e}_1 , \check{e}_2 , $\check{e}_3 \in \text{Fr}(M)$ give the same spin structure, where $-\check{e} = (-e^i)_{i=1}^3$ for $\check{e} = (e^i)_{i=1}^3$.

Proposition 2.5. Two frames $\check{e}, \check{e}_0 \in Fr(M)$ are homotopic to each other if and only if they give the same spin structure and satisfy $H(\check{e}, \check{e}_0) = 0$.

Proof. It is trivial that the former implies the latter.

Suppose the latter holds for $\check{e}, \check{e}_0 \in \operatorname{Fr}(M)$. Then, we have $s(\check{e}, \check{e}_0) = 0$ and $H(\check{e}, \check{e}_0) = 0$. Fix a structure of a CW complex on M with a unique 3-cell. Let M_2 be the 2-skeleton of M. Since $\operatorname{Spin}(3)$ is homeomorphic to S^3 , the lift $\widetilde{\Phi}(\check{e}, \check{e}_0)$ of $\Phi(\check{e}, \check{e}_0)$ is homotopic to a map F such that $F|_{M_2}$ is a constant map. Since the quotient space M/M_2 also is homeomorphic to S^3 , the assumption $H(\check{e}, \check{e}_0) = 0$ implies that F is homotopic to a constant map. Therefore, \check{e} is homotopic to \check{e}_0 . \square

2.2. \mathcal{R} -components and gluing of total foliations. In the rest of the paper, we identify the circle S^1 with \mathbb{R}/\mathbb{Z} , and the two-dimensional torus \mathbb{T}^2 with $(\mathbb{R}/\mathbb{Z})^2$. The sum a+b is well-defined for $a\in S^1$ and $b\in S^1$ or \mathbb{R} . For $a\in S^1$ and $\epsilon_1,\epsilon_2\in\mathbb{R}$, we denote the subset $\{a+t\in S^1\mid t\in [\epsilon_1,\epsilon_2]\}$ by $[a+\epsilon_1,a+\epsilon_2]$. We will abuse the identification of the number $t\in [0,1]$ and $t+\mathbb{Z}\in S^1$ when the meaning is clear.

Put $D^2(r) = \{(x, y) \in \mathbb{R}^2 \mid x^2 + y^2 \le r^2\}$ for $r \ge 0$ and $D^2 = D^2(1)$. We denote $[0, 1] \times \mathbb{T}^2$ by $W, S^1 \times D^2$ by Z, and the origin of \mathbb{R}^2 by Z. We also denote by [a, b] the open interval $\{x \in \mathbb{R} \mid a < x < b\}$.

For a foliation \mathcal{F} on a manifold X and a point p of X, let $\mathcal{F}(p)$ denote the leaf containing p. For a diffeomorphism F from X to another manifold X', let $F(\mathcal{F})$ denote a foliation on X' such that the leaf containing F(p) is $F(\mathcal{F}(p))$. For a pair $(\mathcal{F}^1, \mathcal{F}^2)$ of mutually transverse codimension-one foliations on a three-dimensional manifold M, let $\mathcal{F}^1 \cap \mathcal{F}^2$ be the one-dimensional foliation $\{\mathcal{F}^1(p) \cap \mathcal{F}^2(p)\}_{p \in M}$.

Definition 2.6. Let M be a three-dimensional manifold. We say a subset R of M is a *thick Reeb component* of a foliation \mathcal{F} if R contains a Reeb component R' and $\mathcal{F}|_{\overline{R \setminus R'}}$ is diffeomorphic to a product foliation $\{t \times \mathbb{T}^2\}_{t \in [0,1]}$ on W.

Let (t, x, y) be the standard coordinate system of $S^1 \times \mathbb{R}^2$. Take a smooth odd function χ_R on \mathbb{R} so that $0 < \chi_R(x) < 1$ if $x \in]1/2, 3/2[$ and $\chi_R(x) = 0$ otherwise. Let $\widehat{\mathcal{R}}^1$ and $\widehat{\mathcal{R}}^2$ be the foliations on $S^1 \times \mathbb{R}^2$ that are generated by the kernel of $dy - \chi_R(y)dt$ and $dx - \chi_R(x)dt$, respectively.

We denote by \mathcal{R}^i the restriction of $\widehat{\mathcal{R}}^i$ on Z for i=1,2. We can take a foliation \mathcal{R}^3 on Z so that it is a thick Reeb component and $(\mathcal{R}^i)_{i=1}^3$ is a total foliation. See Figure 1.

Figure 1. Foliations \mathcal{R}^1 , \mathcal{R}^2 , \mathcal{R}^1_T , and \mathcal{R}^2_T .

Definition 2.7. Let $(\mathcal{F}_i)_{i=1}^3$ be a total foliation on a three-dimensional manifold M. We call a subset R of M an \mathcal{R} -component of $(\mathcal{F}^i)_{i=1}^3$ if there exists a diffeomorphism $\psi \colon Z \to R$ such that $\psi(\mathcal{R}^i) = \mathcal{F}^i|_R$ for i=1,2,3 and the restriction of \mathcal{F}^3 on a neighborhood of ∂R is diffeomorphic to $\{t \times \mathbb{T}^2\}_{t \in [0,1]}$ on W. The diffeomorphism ψ is called a *canonical coordinate* of R. The curve $C(R) = \psi(S^1 \times 0)$ admits a natural orientation induced from ψ and we call it the *core* of R.

Remark that the isotopy class of C(R) is uniquely determined as an oriented knot in M.

Let $\varphi_{\mathcal{R}} \colon \mathbb{T}^2 \to S^1 \times \partial D^2$ be the map given by

$$\varphi_{\mathcal{R}}(x, y) = (x, \cos(2\pi y), \sin(2\pi y)).$$

We define foliations \mathcal{R}_T^1 and \mathcal{R}_T^2 on \mathbb{T}^2 so that $\varphi_{\mathcal{R}}(\mathcal{R}_T^i)$ is the restriction of \mathcal{R}^i on ∂Z for each i=1,2. We use the following lemma in Section 4.

Lemma 2.8. If a smooth line field ξ on \mathbb{T}^2 is sufficiently C^0 -close to $T\mathcal{R}^1_T$, then there exists a closed curve which is tangent to ξ and homotopic to the curve $S^1 \times y_0$, where y_0 be the point of S^1 represented by 0.

Proof. Put $A = S^1 \times [y_0 - 1/4, y_0 + 1/4]$. If a smooth line field ξ on \mathbb{T}^2 is sufficiently C^0 -close to $T\mathcal{R}_T^1$, then it is isotopic to ∂A and admits an orientation which directs inward at ∂A . By the Poincaré–Bendixon theorem, there exists a closed curve in A which is tangent to ξ and isotopic to $S^1 \times y_0$.

Let $a_{\mathcal{R}}$ be the integral homology class in $H_1(\mathbb{T}^2, \mathbb{Z})$ represented by a map $x \mapsto (x, 0)$. Remark that each closed leaf of \mathcal{R}_T^1 is the image of a curve which represents $a_{\mathcal{R}}$.

Definition 2.9. Let $(\mathcal{F}^i)_{i=1}^3$ be a total foliation on a manifold M. We call a boundary component T of M an \mathcal{R} -boundary if there exists a diffeomorphism $\psi_T \colon \mathbb{T}^2 \to T$ such that $\psi_T(\mathcal{R}_T^i)$ is the restriction of \mathcal{F}^i to T for i=1,2, and \mathcal{F}^3 is diffeomorphic to the product foliation $\{t \times \mathbb{T}^2\}_{t \in [0,1]}$ on a neighborhood of T. For an \mathcal{R} -boundary component T, we define $a_{\mathcal{R}}(T) \in H_1(T,\mathbb{Z})$ by $a_{\mathcal{R}}(T) = (\psi_T)_*(a_{\mathcal{R}})$.

Remark that if R is an \mathcal{R} -component of a total foliation on a manifold M, then ∂R is an \mathcal{R} -boundary of both R and $\overline{M \setminus R}$.

We define cut and paste operations of total foliations with \mathcal{R} -boundary by following the idea described in [10]. First, we show that the pair $(\mathcal{F}^1|_T, \mathcal{F}^2|_T)$ of foliations of an \mathcal{R} -boundary of a total foliation $(\mathcal{F}^i)_{i=1}^3$ is determined by $a_{\mathcal{R}}(T)$ up to isotopy.

Lemma 2.10. Let F be a diffeomorphism of \mathbb{T}^2 such that $F_*(a_{\mathcal{R}}) = a_{\mathcal{R}}$. Then, there exists a diffeomorphism G which is isotopic to the identity and satisfies $G(\mathcal{R}_T^i) = F(\mathcal{R}_T^i)$ for i = 1, 2.

Proof. Let τ_y be the diffeomorphism of \mathbb{T}^2 such that $\tau_y(x,y)=(x,-y)$. Then, $\tau_y(\mathcal{R}^i_T)=\mathcal{R}^i_T$ for i=1,2 and $(\tau_y)_*(a_{\mathcal{R}})=a_{\mathcal{R}}$. Hence, we may assume that F is orientation-preserving by replacing F with $F\circ\tau_y$ if it is necessary.

Fix an integer k. Let \tilde{h} be a smooth function on $\mathbb{R} \times [0, 1]$ such that $\tilde{h}(y + n, t) = \tilde{h}(y, t) + kn$ for any $(y, t) \in \mathbb{R} \times [0, 1]$ and $n \in \mathbb{Z}$, and

$$\tilde{h}(y,t) = \begin{cases} kn & \text{if } y \in [n, n + (1/32)], \\ k(n+t) & \text{if } y \in [n + (1/16), n + (1/4)], \\ k(n+1) & \text{if } y \in [n + (9/32), n + 1] \end{cases}$$

for any $n \in \mathbb{Z}$ and $t \in [0, 1]$. See Figure 2. The function \tilde{h} induces a map $h \colon S^1 \times [0, 1] \to S^1$. Remark that $h(\cdot, t) \colon S^1 \to S^1$ is a map of degree k.

For $t \in [0, 1]$, we define a diffeomorphism $F_{k,t}$ of \mathbb{T}^2 by

$$F_{k,t}(x, y) = (x + h(y, t), y).$$

Since F is orientation-preserving and $F_*(a_{\mathcal{R}}) = a_{\mathcal{R}}$, F is isotopic to $F_{k,1}$ for some $k \in \mathbb{Z}$. Hence, it is sufficient to show that there exists a diffeomorphism G of \mathbb{T}^2 which is isotopic to the identity and satisfies $G(\mathcal{R}^i_T) = F_{k,1}(\mathcal{R}^i_T)$ for i = 1, 2.

Figure 2. The map $h(\cdot, t)$ and the foliation $F_{k,1}(\mathcal{R}^1)$ for k = 1.

Since $\mathcal{R}^1_T(x,y_1)=S^1\times y_1$ for $y_1\in[0,1/16]$ and $\mathcal{R}^2_T(x,y_2)=S^1\times y_2$ for $y_2\in[1/4,5/16]$, we have $F_{k,0}(\mathcal{R}^2_T)=\mathcal{R}^2_T$ and $F_{k,1}(\mathcal{R}^1_T)=\mathcal{R}^1_T$. The foliations \mathcal{R}^1_T and \mathcal{R}^2_T are invariant under the translation $(x,y)\mapsto (x+t,y)$. It implies that $F_{k,t}(\mathcal{R}^2_T)$ is transverse to \mathcal{R}^1_T for any $t\in[0,1]$. We define an isotopy $\{G_t\}_{t\in[0,1]}$ by $G_t(x,y)\in\mathcal{R}^1_T(x,y)\cap F_{k,t}(\mathcal{R}^2_T(x,y))$. Then, the map G_0 is the identity, $G_1(\mathcal{R}^1_T)=\mathcal{R}^1_T=F_{k,1}(\mathcal{R}^1_T)$, and $G_1(\mathcal{R}^2_T)=F_{k,1}(\mathcal{R}^2_T)$.

Proposition 2.11. For k=1,2, let M_k be a three-dimensional manifold with a toral boundary T_k and $(\mathcal{F}_k^i)_{i=1}^3$ a total foliation of M_k such that T_k is an \mathcal{R} -boundary. Suppose that a diffeomorphism $\psi: T_1 \to T_2$ satisfies $\psi_*(a_{\mathcal{R}}(T_1)) = a_{\mathcal{R}}(T_2)$. Then, there exists a total foliation $(\mathcal{F}^i)_{i=1}^3$ on $M_1 \cup_{\psi} M_2 = M_1 \cup M_2/[p \sim \psi(p)]$ and diffeomorphisms $F_1: M_1 \to M_1$ and $F_2: M_2 \to M_2$ such that F_k is isotopic to the identity and $F_k(\mathcal{F}_k^i) = \mathcal{F}^i|_{M_k}$ for any i=1,2,3 and k=1,2.

Proof. By Lemma 2.10, we can isotope $(\mathcal{F}_2^i)_{i=1}^3$ so that it is compatible with $(\mathcal{F}_1^i)_{i=1}^3$ on a neighborhood of $T_1 = T_2$ in $M_1 \cup_{\psi} M_2$.

2.3. Knotted \mathcal{R} -components and surgery. Let M be an oriented three-dimensional manifold. For a smooth link L in M, let Fr(L;M) be the set of vector fields $v: L \to TM$ on L satisfying $v(p) \not\in T_pL$ for any $p \in L$. A framing of L is a connected component of Fr(L;M). An oriented knot K is null-homologous if and only if it admits a Seifert surface S, that is, an oriented embedded surface with $\partial S = K$.

Definition 2.12. Suppose an oriented knot K admits a Seifert surface S. We call an orientation preserving embedding $\psi \colon S^1 \times D^2 \to M$ an n-framed tubular coordinate of K if the restriction of ψ to $S^1 \times \{(0,0)\}$ is an orientation preserving diffeomorphism onto K and the algebraic intersection number of S and $\psi(S^1 \times \{(1,0)\})$ is n. The framing represented by a vector field $v \in Fr(K; M)$ tangent to $\psi(S^1 \times [-1,1] \times \{0\})$ is called an n-framing of K.

It is known that the n-framing of K does not depend on the choices of S and ψ . If a link L is tangent to leaves of a foliation \mathcal{F} , then a vector field v_L on L with $v_L(p) \in T_p\mathcal{F} \setminus T_pL$ gives a framing of L. We call it the *framing given by* \mathcal{F} . We say an \mathcal{R} -component R of a total foliation $(\mathcal{F}^i)_{i=1}^3$ on M is *null-homotopic* if the core C(R) is null-homotopic. In addition, if \mathcal{F}^1 gives the n-framing of C(R), we say that R is an n-framed null-homotopic \mathcal{R} -component. A knot is called *unknotted* if it bounds an embedded disk. We say an \mathcal{R} -component of a total foliation on M is *unknotted* if the core is unknotted.

Suppose that a total foliation $(\mathcal{F}^i)_{i=1}^3$ on M admits an \mathcal{R} -component R. Let $\mu(R) \in H_1(\partial R, \mathbb{Z})$ be the homology class represented by a meridian of R. Up to isotopy, there exists a unique diffeomorphism F on ∂R such that $F_*(a_{\mathcal{R}}(\partial R)) = a_{\mathcal{R}}(\partial R)$ and $F_*(\mu(R)) = \mu(R) + a_{\mathcal{R}}(\partial R)$. We call $M_R = (\overline{M} \setminus \overline{R} \cup R)/F(p) \sim p$ the manifold obtained by the *standard surgery* along R. By Proposition 2.11, total foliations $(\mathcal{F}^i|_{\overline{M}\setminus \overline{R}})_{i=1}^3$ and $(\mathcal{F}^i|_R)_{i=1}^3$ induce a total foliation $(\mathcal{F}^i_F)_{i=1}^3$. We call $(\mathcal{F}^i_F)_{i=1}^3$ the total foliation obtained by the *standard surgery* along R. In [10], p. 22–24, one can see another surgery along an \mathcal{R} -component, which essentially yields the same total foliation.

Lemma 2.13. If R is null-homotopic and k-framed, then the above M_R is a manifold obtained by a Dehn surgery along C(R) with framing coefficient k+1.

Proof. Since R is k-framed, $\lambda(R) = a_{\mathcal{R}}(\partial R) - k\mu(R)$ is represented by the longitude of C(R) corresponding to the 0-framing. The condition $F_*(\mu(R)) = \lambda(R) + (k+1)\mu(R)$ implies that the coefficient of the Dehn surgery is k+1.

Let $(\mathcal{F}^i)_{i=1}^3$ be a total foliation on S^3 and R_1,\ldots,R_k be its \mathcal{R} -components with the n_1,\ldots,n_k -framings. Lemma 2.13 implies that the manifold obtained by the standard surgery along \mathcal{R} -components R_1,\ldots,R_k is the boundary of the four-dimensional 2-handlebody X whose Kirby diagram is $\bigcup_{j=1}^k C(R)$ with the (n_i+1) -framing on each $C(R_i)$.

As we saw in Subsection 2.1, each total plane field on M defines a spin structure on M. For a total foliation $(\mathcal{F}^i)_{i=1}^3$, we say a spin structure on M is given by $(\mathcal{F}^i)_{i=1}^3$ if it is given by the total plane field $(T\mathcal{F}^i)_{i=1}^3$.

Let $(\mathcal{F}_0^i)_{i=1}^3$ be a total foliation on S^3 with odd-framed \mathcal{R} -components R_1, \ldots, R_k . Let M and $(\mathcal{F}^i)_{i=1}^3$ denote the three-dimensional manifold and the total foliation obtained by the standard surgeries on all R_i 's, and X the four-dimensional 2-handlebody corresponding to the surgery as above. By Proposition 2.1, X admits a unique spin structure s_X .

Proposition 2.14. The restriction of s_X to $M = \partial X$ coincides with the one given by $(\mathcal{F}^i)_{i=1}^3$.

Proof. Let $h_i \subset X$ be the 2-handles corresponding to $C(R_i)$ for $j = 1, \ldots, k$. Total foliations $(\mathcal{F}_0^i)_{i=1}^3$ and $(\mathcal{F}^i)_{i=1}^3$ define a spin structure s_* on a neighborhood of $S^3 \cup M = \partial D^4 \cup \partial X$ in $X = D^4 \cup \bigcup_{j=1}^k h_j$, where D^4 is the four-dimensional ball. Since $H_1(S^3, \mathbb{Z}_2) = 0$, the sphere S^3 admits a unique spin structure. It is known that it extends to D^4 . The closure of a connected component of $X \setminus (S^3 \cup M)$ is either the ball D^4 or a 2-handle h_i . Since they are homeomorphic to the four dimensional ball, the spin structure on $S^3 \cup M$ can be extended to X. By the uniqueness of a spin structure on a 2-handlebody, it completes the proof.

2.4. Gluing formula of the difference of Hopf invariant. For two total foliations $(\mathcal{F}^i)_{i=1}^3$ and $(\mathcal{F}^i)_{i=1}^3$ which give the same spin structure, we denote the difference of Hopf invariant of the corresponding orthonormal frames (see Definition 2.4) by $H((\mathcal{F}^i)_{i=1}^3, (\mathcal{G}^i)_{i=1}^3).$

Definition 2.15. The positive total Reeb foliation $(\mathcal{R}^i_+)_{i=1}^3$ is a total foliation on S^3 which is the union of two (-1)-framed unknotted \mathcal{R} -components.

Remark that each \mathcal{R}^i_+ is a thick Reeb foliation and the cores of two \mathcal{R} -components form a positive Hopf link under the transverse orientation of \mathcal{R}^3_+ .

Let τ_{S^3} be an orientation reversing diffeomorphism on S^3 . It is known that $H((\mathcal{R}_+^i)_{i=1}^3, \tau_{S^3}(\mathcal{R}_+^i)_{i=1}^3) = 1$ (see *e.g.* Lemma 24 in [4]). By formulae (1) and (2) on page 276, we have

$$H((\tau_{S^3}(\mathcal{F}^i))_{i=1}^3, (\mathcal{R}_+^i)_{i=1}^3) = -1 - H((\mathcal{F}^i)_{i=1}^3, (\mathcal{R}_+^i)_{i=1}^3), \tag{3}$$

for any total foliation $(\mathcal{F}^i)_{i=1}^3$ on S^3 . Let $(\mathcal{F}^i)_{i=1}^3$ and $(\mathcal{G}^i)_{i=1}^3$ be total foliations on M and S^3 , respectively. Suppose that $(\mathcal{F}^i)_{i=1}^3$ admits a null-homotopic \mathcal{R} -component R and $(\mathcal{G}^i)_{i=1}^3$ admits a (-1)-framed unknotted \mathcal{R} -component R'. Since both R and $S^3 \setminus R'$ are different and $S^3 \setminus R'$. feomorphic to $S^1 \times D^2$, there exists a diffeomorphism $\psi : \overline{S^3 \setminus R'} \to R$ such that $\psi_*(a_{\mathcal{R}}(\partial R')) = a_{\mathcal{R}}(\partial R)$ and $\psi_*(\mu_{R'}) = \mu_R$. Remark that the isotopy class of ψ is uniquely determined. By Proposition 2.11, there exists a total foliation $(\mathcal{F}^i \cup_{R,R'} \mathcal{G}^i)_{i=1}^3$ on M such that it coincides with $(\mathcal{F}^i)_{i=1}^3$ on $\overline{M \setminus R}$ and with $(\psi(\mathcal{G}^i))_{i=1}^3$ on R up to isotopy.

¹Such a Reeb foliation is called a *positive Reeb foliation*. The orientations given as the core of the Rcomponent and given by the transverse orientation of \mathcal{R}_0^3 are opposite on one of the cores.

Proposition 2.16. In the above situation, we have

$$H((\mathcal{F}^i \cup_{R,R'} \mathcal{G}^i)_{i=1}^3, (\mathcal{F}^i)_{i=1}^3) = H((\mathcal{G}^i)_{i=1}^3, (\mathcal{R}^i_+)_{i=1}^3). \tag{4}$$

Proof. First, we notice that if two frames \check{e} and \check{e}' on a three-dimensional manifold M' gives the same spin structure, then $H(\check{e},\check{e}')$ is equal to the algebraic intersection number of the submanifolds $\{\check{e}(p)\mid p\in M'\}$ and $\{-\check{e}'(p)\mid p\in M'\}$ of the orthonormal frame bundle of M'.

For convenience, fix Riemannian metrics on M and S^3 so that ψ is an isometry between $\overline{S^3 \setminus R'}$ and R. Let $\check{e}_{\mathcal{F}}$, $\check{e}_{\mathcal{G}}$, $\check{e}_{\mathcal{R}}$, \check{e}_* be the orthonormal frames induced from $(\mathcal{F}^i)_{i=1}^3$, $(\mathcal{G}^i)_{i=1}^3$, $(\mathcal{R}^i_+)_{i=1}^3$, and $(\mathcal{F}^i \cup_{R,R'} \mathcal{G}^i)_{i=1}^3$, respectively. By modifying $(\mathcal{R}^i_+)_{i=1}^3$ in its isotopy class, we may assume that R' is a (-1)-framed \mathcal{R} -component of $(\mathcal{R}^i_+)_{i=1}^3$ and $\psi(\check{e}_{\mathcal{R}}|_{\overline{S^3 \setminus R'}}) = \check{e}_{\mathcal{F}}|_R$. Take submanifolds $\Lambda = \{\check{e}_{\mathcal{G}}(p) \mid p \in S^3\}$ and $\Lambda' = \{-\check{e}_{\mathcal{R}}(p) \mid p \in S^3\}$ of the orthonormal frame bundle of S^3 . Let Fr ψ be the map between the frame bundles on $S^3 \setminus R'$ and R induced by ψ . Then, we have $\mathrm{Fr}\,\psi(\Lambda) = \{\check{e}_*(p) \mid p \in R\}$ and $\mathrm{Fr}\,\psi(\Lambda') = \{-\check{e}_{\mathcal{F}}(p) \mid p \in R\}$. Since $(\mathcal{F}^i \cup_{R,R'} \mathcal{G}^i)|_{\overline{M \setminus R}} = \mathcal{F}^i|_{\overline{M \setminus R}}$, we also have

Fr
$$\psi(\Lambda \cap \Lambda') = \{ \check{e}_*(p) \mid p \in M \} \cap \{ -\check{e}_{\mathscr{F}}(p) \mid p \in M \}.$$

This implies formula (4).

3. Construction of total foliations

3.1. Braids in W. Let $SL(2,\mathbb{Z})$ denote the group of 2×2 -integer matrices with determinant one, and I denote the identity matrix in $SL(2,\mathbb{Z})$. Each element A of $SL(2,\mathbb{Z})$ acts on \mathbb{T}^2 as a diffeomorphism.

Fix $n \ge 1$ and define the points $Q_i = (j/n, j/n) + \mathbb{Z}^2 \in \mathbb{T}^2$ for $j = 0, \dots, n-1$.

Definition 3.1. For $A \in SL(2,\mathbb{Z})$ and $n \geq 1$, we say $\Gamma \subset [0,1] \times \mathbb{T}^2$ is a *smooth n-braid twisted by A* if there exists a map $\gamma \colon \{0,\ldots,n-1\} \times [0,1] \to \mathbb{T}^2$ and a permutation σ on $\{0,\ldots,n-1\}$ such that

- $\Gamma = \{(t, \gamma(j, t)) \mid (j, t) \in \{0, \dots, n-1\} \times [0, 1]\}.$
- $\gamma(j,t) \neq \gamma(j',t)$ for any $t \in [0,1]$ if $j \neq j'$, and
- $\gamma(j,\varepsilon) = Q_j$ and $\gamma(j,1-\varepsilon) = A \cdot Q_{\sigma(j)}$ for any $j=0,\ldots,n-1$ and any sufficiently small $\varepsilon \geq 0$.

We call a subset $\Gamma^j = \{(t, \gamma(j, t)) \mid t \in [0, 1]\}$ the *j-th string of* Γ . Let $B_n(A)$ be the set of all smooth *n*-braids twisted by A.

We can identify $B_n(A)$ with a set of smooth maps from $\{0, \ldots, n-1\} \times [0, 1]$ to \mathbb{T}^2 . This identification induces a topology on $B_n(A)$. Let $\pi_0(B_n(A))$ be the set of connected components of $B_n(A)$.

For $A \in SL(2,\mathbb{Z})$, let F_A be the diffeomorphism on W given by $F_A(t,w) = (t, A \cdot w)$. We define $\tau_1(t,w) = (1-t,w)$, $\tau_-(t,w) = (t/2,w)$, and $\tau_+(t,w) = ((1+t)/2,w)$ for $(t,w) \in W = [0,1] \times \mathbb{T}^2$.

Definition 3.2. Let Γ be a braid in $B_n(A)$.

- The inverse $\Gamma^{-1} \in B_n(A^{-1})$ is defined by $\Gamma^{-1} = F_{A^{-1}} \circ \tau_1(\Gamma)$.
- The composition $\Gamma * \Gamma' \in B_n(A' \cdot A)$ for $\Gamma \in B_n(A)$ and $\Gamma' \in B_n(A')$ is defined by $\Gamma * \Gamma' = \tau_-(\Gamma) \cup (F_A \circ \tau_+)(\Gamma')$.

They induce corresponding operations on $\pi_0(B_n(A))$. We can see that they define a group structure on $\pi_0(B_n(I))$, which is isomorphic to the *braid group of n-strings* on \mathbb{T}^2 . The composition also defines a free and transitive action of $\pi_0(B_n(I))$ on $\pi_0(B_n(A))$. In particular, each element of $\pi_0(B_n(A))$ gives a bijective map between $\pi_0(B_n(I))$ and $\pi_0(B_n(A))$.

3.2. Total foliations with braided leaves. In this subsection, we fix an integer $n \geq 1$ and a real number $\eta > 0$ which is sufficiently smaller than 1/n, for example, $\eta = (100n)^{-1}$. Put $q_j = (j/n) + \mathbb{Z} \in S^1$ for $j = 0, \ldots, n-1$. Recall that $Q_j = (q_j, q_j) \in \mathbb{T}^2$.

First, we define the standard total foliation $(\mathcal{F}_{\mathrm{std}}^i)_{i=1}^3$ on $W = [0,1] \times \mathbb{T}^2$. Let (t,x,y) be the standard coordinate system of $W = [0,1] \times \mathbb{T}^2$. Fix a smooth function $\bar{\chi}_1$ on \mathbb{R} such that $0 < \bar{\chi}_1(x) < \eta$ for $x \in]1/16n, 1/8n[$ and $\bar{\chi}_1(x) = 0$ otherwise. Let χ_1 be the function on S^1 given by $\chi_1(q_j + x) = \bar{\chi}_1((1/2n) + x) - \bar{\chi}_1((1/2n) - x)$ for any $j = 0, \ldots, n-1$ and $x \in [0,1/n]$. See Figure 3. We define 1-forms ω_{std}^1 ,

Figure 3. Function χ_1 .

 $\omega_{\rm std}^2$, and $\omega_{\rm std}^3$ on W by

$$\omega_{\text{std}}^{1}(t, x, y) = dy - \chi_{1}(y)dx,$$

$$\omega_{\text{std}}^{2}(t, x, y) = dx - \chi_{1}(x)dy,$$

$$\omega_{\text{std}}^{3}(t, x, y) = dt - (\bar{\chi}_{1}(t - 3/8) + \bar{\chi}_{1}(t - 5/8))dy.$$

Let $\mathcal{F}_{\mathrm{std}}^i$ be the foliation generated by the kernel of ω_{std}^i for i=1,2,3. See Figure 4. It is easy to check that the triple $(\mathcal{F}_{\mathrm{std}}^i)_{i=1}^3$ is a total foliation.

Figure 4. Total foliation $(\mathcal{F}_{std}^i)_{i=1}^3$ on $[0,1] \times [j/n,(j+1)/n]^2$.

Definition 3.3. Let R be an embedded solid torus in M and \mathcal{F} a foliation on $\overline{M \setminus R}$. We say a foliation \mathcal{F}_* is obtained by a turbularization of \mathcal{F} along R if R is a thick Reeb component of \mathcal{F}_* and there exists a diffeomorphism ψ of the open manifold $M \setminus R$ which is isotopic to the identity and satisfies $\mathcal{F}_*|_{M \setminus R} = \psi(\mathcal{F})$.

Observe that if the restriction of $\mathcal F$ to R is isotopic to the product foliation $\{\{\operatorname{pt}\}\times D^2\}$, then we can turbularize $\mathcal F$ along R.

Let U_j be the interior of $[1/4,1/3] \times [q_j+(1/4n),q_j+(3/4n)] \times S^1$ for $j=0,\ldots,n-1$ and

$$W_0 = W \setminus \bigcup_{j=0}^{n-1} U_j.$$

Definition 3.4. We say a foliation \mathcal{F}_0 on a subset W' of W is almost horizontal if

$$T\mathcal{F}_0(p) \subset \{v \in T_p W' \mid dy(v)^2 \leq \eta^{-2} (dt(v)^2 + dx(v)^2)\}$$

for any $p \in W'$.

The next proposition shows how to make almost horizontal foliations part of a total foliation.

Proposition 3.5. For any given almost horizontal foliation \mathcal{F} on W_0 , there exists an extension \mathcal{F}^1 of \mathcal{F} to W such that $(\mathcal{F}^1, \mathcal{F}^2_{std}, \mathcal{F}^3_{std})$ is a total foliation.

Proof. Put

$$R_j^+ = \{ ((3/8) + t, q_j + (1/2n) + x) \mid (t, x) \in D^2(1/8n) \} \times S^1,$$

$$R_j^- = \{ ((5/8) + t, q_j + (1/2n) + x) \mid (t, x) \in D^2(1/8n) \} \times S^1$$

for j = 0, ..., n - 1. Let f_i be a diffeomorphism of S^1 which is conjugate to the holonomy map of \mathcal{F} along the torus ∂U_i . By r_{α} , we denote the rigid rotation of

Figure 5. The sets W_0 and R_i^{\pm} .

angle $\alpha \in \mathbb{R}$, *i.e.*, $r_{\alpha}(y) = y + \alpha$. By a consequence of the Fundamental Theorem of Herman (see *e.g.* [3], Corollary 8.5.3), there exist $\alpha_i^-, \alpha_i^+ \in \mathbb{R}$ and a diffeomorphism g_j on S^1 such that $f_j=(g_j\circ r_{\alpha_j^-}\circ g_j^{-1})\circ r_{\alpha_j^+}$ for any $j=0,\ldots,n-1$. It implies that

we can extend $\mathscr F$ to an almost horizontal foliation $\mathscr G$ on $\overline{W\setminus \bigcup_{j=0}^{n-1}(R_j^-\cup R_j^+)}$ such that the holonomy map of \mathscr{G} along the torus ∂R_i^{σ} is conjugate to the rigid rotation $r_{\alpha_i^{\sigma}}$ for any $j=0,\ldots,n-1$ and $\sigma=\pm.$ Since $\mathscr G$ is almost horizontal, it is transverse to $\mathcal{F}^2_{
m std}$ and $\mathcal{F}^3_{
m std}$. A turbularization of \mathscr{G} along all R_i^\pm gives a foliation \mathscr{F}^1 on W which is transverse to both \mathcal{F}_{std}^2 and \mathcal{F}_{std}^3 . See Figure 6.

Recall that $F_A(t, w) = (t, Aw), \tau_1(t, w) = (1 - t, w), \tau_-(t, w) = (t/2, w),$ and $\tau_+(t,w)=((t+1)/2,w)$ for $A\in \mathrm{SL}(2,\mathbb{Z})$ and $(t,w)\in W.$ Let (e_t,e_x,e_s) be the orthonormal frame on W which corresponds to the standard coordinates (t, x, y).

Definition 3.6. For $A \in SL(2,\mathbb{Z})$, let tFol(A) be the set of total foliations $(\mathcal{F}^i)_{i=1}^3$ on W such that

- \mathcal{F}^3 is transverse to e_t .
- $\mathcal{F}^i = \mathcal{F}^i_{\mathrm{std}}$ on a neighborhood of $\{0\} \times \mathbb{T}^2$ for i = 1, 2, 3, $\mathcal{F}^i = F_A(\mathcal{F}^i_{\mathrm{std}})$ on a neighborhood of $\{1\} \times \mathbb{T}^2$ for i = 1, 2, 3

Figure 6. Total foliation associated to an extension of \mathcal{F}_0 .

We introduce some operations on total foliations in tFol(A).

Definition 3.7. Let $(\mathcal{F}^i)_{i=1}^3$ and $(\mathcal{G}^i)_{i=1}^3$ be total foliations in tFol(A) and tFol(A') respectively.

- The inverse $((\mathcal{F}^i)^{-1})_{i=1}^3\in \mathsf{tFol}(A^{-1})$ is defined by $(\mathcal{F}^i)^{-1}=F_{A^{-1}}\circ au_1(\mathcal{F}^i)$ for i = 1, 2, 3.
- The composition $(\mathcal{F}^i * \mathcal{G}^i)_{i=1}^3 \in \mathrm{tFol}(A'A)$ of $(\mathcal{F}^i)_{i=1}^3$ and $(\mathcal{G}^i)_{i=1}^3$ is defined by $(\mathcal{F}^i * \mathcal{G}^i)|_{[0,1/2]} = \tau_-(\mathcal{F}^i)$ and $(\mathcal{F}^i * \mathcal{G}^i)|_{[1/2,1]} = (\tau_+ \circ F_A)(\mathcal{G}^i)$.

We define an important subset of tFol(A) consisting of total foliations with *braided* leaves.

Definition 3.8. For $A \in SL(2,\mathbb{Z})$, we denote by tFol(A,n) the subset of tFol(A)consisting of total foliations $(\mathcal{F}^i)_{i=1}^3$ such that $\Gamma = \bigcup_{i=0}^{n-1} (\mathcal{F}^1 \cap \mathcal{F}^2)(0, Q_i)$ is an element of $B_n(A)$. For $(\mathcal{F}^i)_{i=1}^3 \in \mathrm{tFol}(A,n)$, we denote the connected component of $B_n(A)$ containing the above Γ by $\sigma((\mathcal{F}^i)_{i=1}^3)$.

For any given $(\mathcal{F}^i)_{i=1}^3\in \mathrm{tFol}(A,n)$ and $(\mathcal{G}^i)_{i=1}^3\in \mathrm{tFol}(A',n)$, it is easy to verify that $((\mathcal{F}^i)^{-1})_{i=1}^3$ is an element of $\mathrm{tFol}(A^{-1},n)$ with $\sigma(((\mathcal{F}^i)^{-1})_{i=1}^3)=\sigma((\mathcal{F}^i)_{i=1}^3)^{-1}$ and $(\mathcal{F}^i*\mathcal{G}^i)_{i=1}^3$ is an element of $\mathrm{tFol}(A'A,n)$ with $\sigma(((\mathcal{F}^i*\mathcal{G}^i)_{i=1}^3))=\sigma((\mathcal{F}^i)_{i=1}^3)*\sigma((\mathcal{G}^i)_{i=1}^3)$. Let $(\mathcal{F}^i)_{i=1}^3$ be a total foliation in $\mathrm{tFol}(A,n)$. Put $\Gamma^j=\mathcal{F}^1\cap\mathcal{F}^2(0,Q_j)$ for $j=0,\ldots,n-1$. For each k=1,2 and each $j=0,\ldots,n-1$, there exists a smooth function θ_k^j on Γ^j such that

$$\cos(2\pi\theta_k^j(p))e_x(p)+\sin(2\pi\theta_k^j(p))e_y(p)\in T\mathcal{F}^k(p)$$

for any $p \in \Gamma^j$. We define the rotation $\Theta_k((\mathcal{F}^i)_{i=1}^3, j)$ of \mathcal{F}^k along the j-th string

$$\Theta_k((\mathcal{F}^i)_{i=1}^3,j) = \theta_k^j(1,w_1^j) - \theta_k^j(0,w_0^j),$$

where $\{(0, w_0^j), (1, w_1^j)\} = \partial \Gamma^j$. It does not depend on the choice of θ_k^j .

For any sufficiently small $\delta>0$ and $j=0,\ldots,n-1$, there exist two maps f and g from $[-2\delta,2\delta]$ to $\mathbb R$ such that the holonomy of $\mathcal F^1\cap\mathcal F^2$ along Γ^j is given by the map $(0,w_0^j+(x,y))\mapsto (1,w_1^j+A\cdot(f(x),g(y)))$. We define the δ -normalized holonomy of $\mathcal F^1\cap\mathcal F^2$ along j-th string by the pair $(H_x^\delta((\mathcal F^i)_{i=1}^3,j),H_y^\delta((\mathcal F^i)_{i=1}^3,j))$ of maps from [-2,2] to $\mathbb R$ given by

$$H_x^\delta((\mathcal{F}^i)_{i=1}^3,j)(x)=\delta^{-1}\cdot f(\delta x),\quad H_y^\delta((\mathcal{F}^i)_{i=1}^3,j)(y)=\delta^{-1}\cdot g(\delta y).$$

We denote by $Diff_0([-2,2],0)$ the set of diffeomorphisms f on [-2,2] such that f(0) = 0 and $\{f(x) \neq x\} \subset [-2,2]$.

Proposition 3.9. For any $A \in SL(2, \mathbb{Z})$, $\sigma \in \pi_0(B_n(A))$, $m \in \mathbb{Z}$, and any sequences $(f_j)_{j=0}^{n-1}$ and $(g_j)_{j=0}^{n-1}$ in $Diff_0([-2,2],0)$, there exists $(\mathcal{F}^i)_{i=1}^3 \in tFol(A,n)$ and $\delta > 0$ such that

- $\sigma((\mathcal{F}^i)_{i=1}^3) = \sigma$,
- $\Theta((\mathcal{F}^i)_{i=1}^3, j)$ does not depend on j and belongs to the interval [m, m+1[, and
- $H_x^\delta((\mathcal{F}^i)_{i=1}^3, j) = f_j$ and $H_y^\delta((\mathcal{F}^i)_{i=1}^3, j) = g_j$ for any $j = 0, \dots, n-1$.

The rest of the subsection is devoted to the proof of the proposition. We divide it into several lemmas. Put

$$A_{xy} = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, A_1 = \begin{pmatrix} 1 & 0 \\ 1 & 1 \end{pmatrix}, A_2 = \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix}, A_* = \begin{pmatrix} 0 & -1 \\ 1 & 1 \end{pmatrix}.$$
 (5)

They satisfy the following relations:

$$A_{xy}^2 = I, \ A_{xy} \cdot A_1 \cdot A_{xy} = A_2, \ A_* = A_2^{-1} \cdot A_1, \ A_*^3 = -I.$$
 (6)

Lemma 3.10. The triple $(F_{A_{xy}}(\mathcal{F}^2), F_{A_{xy}}(\mathcal{F}^1), F_{A_{xy}}(\mathcal{F}^3))$ is a total foliation in $tFol(A_{xy} \cdot A \cdot A_{xy})$ for any $(\mathcal{F}^i)_{i=1}^3 \in tFol(A)$. Moreover, if $(\mathcal{F}^i)_{i=1}^3 \in tFol(A, n)$, then the above triple is in $tFol(A_{xy} \cdot A \cdot A_{xy}, n)$.

Proof. It is an easy consequence of the identities $F_{A_{xy}}(\mathcal{F}_{std}^1) = \mathcal{F}_{std}^2$ and $F_{A_{xy}}(\mathcal{F}_{std}^2) = \mathcal{F}_{std}^1$.

Let σ_0 be the connected component of $B_n(I)$ represented by the constant braid $\Gamma_0 = [0,1] \times \{Q_1,\ldots,Q_{n-1}\}$. The following lemma is an interpretation of the construction in [10] (p. 49–50) in our setting.

Lemma 3.11. For any given $\delta_0 > 0$ and any sequences $(f_j)_{j=0}^{n-1}$ and $(g_j)_{j=0}^{n-1}$ in $\mathrm{Diff}_0([-2,2],0)$ there exist $(\mathcal{F}^i)_{i=1}^3 \in \mathrm{tFol}(I,n)$ and $\delta \in (0,\delta_0)$ such that $\sigma((\mathcal{F}^i)_{i=1}^3) = \sigma_0$, $\Theta_1((\mathcal{F}^i)_{i=1}^3,j) = \Theta_2((\mathcal{F}^i)_{i=1}^3,j) = 0$, $H_x^{\delta}((\mathcal{F}^i)_{i=1}^3,j) = f_j$, and $H_y^{\delta}((\mathcal{F}^i)_{i=1}^3,j) = g_j$ for any $j = 0,\ldots,n-1$.

Proof. Take $\delta \in (0, \min\{\delta_0, 1\})$. First, we fix $j_* \in \{0, \dots, n-1\}$ and a diffeomorphism $g \in \text{Diff}_0([-2,2],0)$ and we show the lemma for the case all f_i 's and g_i 's are the identity except $g_{j_*}=g$. Let us modify \mathcal{F}^1_{std} so as to have the holonomy corresponding to g. Take a smooth map $\chi_2 \colon S^1 \times [1/4, 3/4] \to S^1$ such that

- (1) $\chi_2(y, 1/4 + \epsilon) = y$ and $\chi_2(y, 3/4 \epsilon) = \chi_2(y, 3/4)$ for any $y \in [0, 1]$ and any small $\epsilon \geq 0$,
- (2) $\chi_2(y,t) = y \text{ if } y \notin [q_{j_*} 2\delta, q_{j_*} + 2\delta],$
- (3) $\chi_2(q_{i_*} + y', 3/4) = q_{i_*} + \delta g(\delta^{-1}y')$ for any $y' \in [-\delta, \delta]$,
- (4) $\frac{\partial h}{\partial y}(y,t) > 0$ and $\left| \frac{\partial h}{\partial t}(y,t) \right| < \eta^{-1}$ for any (y,t).

Remark that $\chi_2(\cdot,t)$ is a diffeomorphism of S^1 for any $t\in [1/4,3/4]$. Put $J_{j_*}=[q_{j_*}-(1/4n),q_{j_*}+(1/4n)]\subset S^1$ and $V_{j_*}=[1/4,3/4]\times J_{j_*}\times S^1$. Since $\partial V_{j_*}\cap \operatorname{Int} W_0\subset \{1/4,3/4\}\times J_{j_*}\times S^1$, we can define a foliation \mathscr{F}_0^1 on W_0 such that $\mathscr{F}_0^1|_{W_0\setminus V_{j_*}}=\mathscr{F}_{\operatorname{std}}^1$ and

$$(\mathcal{F}_0^1|_{V_{i_*}})(1/4, x, y) = \{(t, x', \chi_2(y, t)) \mid (t, x') \in [1/4, 3/4] \times J_{i_*}\}$$

for any $(x, y) \in J_{j_*} \times [0, 1]$. See Figure 7. Since $\left|\frac{\partial h}{\partial t}(y, t)\right| < \eta^{-1}$ for any (y, t), the

Figure 7. Foliation $(\mathcal{F}_0^{-1}|_{V_{i*}})$.

foliation \mathcal{F}_0^1 is almost horizontal. By Proposition 3.5, there exists a total foliation $(\mathcal{F}^i)_{i=1}^3 \in \mathrm{tFol}(I)$ such that $\mathcal{F}^1|_{W_0} = \mathcal{F}_0^1$ and $\mathcal{F}^i = \mathcal{F}_{\mathrm{std}}^i$ for i=2,3. Since Γ_0 is tangent to $\mathcal{F}_0^1 \cap \mathcal{F}_0^2$, $(\mathcal{F}^i)_{i=1}^3$ is contained in $\mathrm{tFol}(I,n)$. The holonomy of $\mathcal{F}^1 \cap \mathcal{F}^2$ along the j_* -th string $\Gamma_0^{j_*}$ is

$$(0, q_{j_*} + x, q_{j_*} + y) \mapsto (1, q_{j_*} + x, \chi_2(q_{j_*} + y, 3/4))$$
 for $(x, y) \in [-\delta, \delta]^2$.

Hence, $H_x^{\delta}((\mathcal{F}^i)_{i=1}^3, j_*)$ is the identity map and $H_y^{\delta}((\mathcal{F}^i)_{i=1}^3, j_*) = g$. It is easy to see that $H_x^{\delta}((\mathcal{F}^i)_{i=1}^3,j)$ and $H_y^{\delta}((\mathcal{F}^i)_{i=1}^3,j)$ are the identity maps for all $j\neq j_*$, and $\Theta_1((\mathcal{F}^i)_{i=1}^3,j)=\Theta_2((\mathcal{F}^i)_{i=1}^3,j)=0$ for any $j=0,\ldots,n-1$.

By Lemma 3.10, the total foliation $(F_{A_{xy}}(\mathcal{F}^2), F_{A_{xy}}(\mathcal{F}^1), F_{A_{xy}}(\mathcal{F}^3))$ is contained in tFol(I, n). It easy to verify that it satisfies the required conditions for the case $f_{j_*} = g$ and all the other f_j 's and g_j 's are the identity map. Hence, we can obtain the required total foliation for a general sequence $(f_j, g_j)_{i=0}^{n-1}$ as a composition of the total foliations given by the above construction.

Lemma 3.12. For any given $\sigma \in \pi_0(B_n(I))$, there exists $(\mathcal{F}^i)_{i=1}^3 \in tFol(I,n)$ such that $\sigma((\mathcal{F}^i)_{i=1}^3) = \sigma$ and $\Theta_1((\mathcal{F}^i)_{i=1}^3,j) = \Theta_2((\mathcal{F}^i)_{i=1}^3,j) = 0$ for any $j=0,\ldots,n-1$.

Proof. Fix a smooth function α on [0,1] such that $\alpha(t)=0$ for $t\in[0,1/4], \alpha(t)=0$ 1/n for $t \in [3/4, 1]$, and $0 \le d\alpha/dt(t) \le \eta^{-1}$ for any $t \in [0, 1]$. Put $V_j =$ $[0,1] \times [q_j - (1/4n), q_j + (1/4n)] \times S^1$ and $\Gamma^j(y) = \{(t,q_j,y+\alpha(t)) \mid t \in [0,1]\}$ for $j = 0, \ldots, n-1$ and $y \in S^1$.

First, for any given $m=0,\ldots,n-1$, there exists $(\mathcal{F}_m^i)_{i=1}^3\in \mathsf{tFol}(I)$ such that

- $\mathcal{F}_m^1|_{W_0 \setminus V_m} = \mathcal{F}_{\mathrm{std}}^1|_{W_0 \setminus V_m}, \mathcal{F}_m^2 = \mathcal{F}_{\mathrm{std}}^2$, and $\Gamma^m(y)$ is tangent to $\mathcal{F}_m^1 \cap \mathcal{F}_m^2$ for any $y \in S^1$.

In fact, it can be obtained by the same construction as the total foliation $(\mathcal{F}^i)_{i=1}^3$ in

the proof of Lemma 3.11 by replacing $\chi_2(y,t)$ in the definition of \mathcal{F}_0^1 with $y+\alpha(t)$. Put $\mathcal{G}_m^1=F_{A_{xy}}(\mathcal{F}_m^2),\,\mathcal{G}_m^2=F_{A_{xy}}(\mathcal{F}_m^1),\,$ and $\mathcal{G}_m^3=F_{A_{xy}}(\mathcal{F}_2^3).$ Let $((\mathcal{F}_m^i)^{-1})_{i=1}^3$ and $((\mathcal{G}_m^i)^{-1})_{i=1}^3$ be the inverses of $(\mathcal{F}_m^i)_{i=1}^3$ and $(\mathcal{G}_m^i)_{i=1}^3$ respectively. Remark that all of them are total foliation in tFol(I) by Lemma 3.10.

We define $(\mathcal{F}_{\sigma_m}^i)_{i=1}^3 \in \mathsf{tFol}(I)$ by

$$\mathcal{F}_{\sigma_m}^i = \mathcal{F}_m^i * (\mathcal{F}_{m+1}^i)^{-1} * \mathcal{G}_{m+1}^i * (\mathcal{G}_m^i)^{-1}$$

and put $\sigma_m = \sigma((\mathcal{F}_{\sigma_m}^i)_{i=1}^3)$ for $m = 0, \ldots, n-2$. Then, $(\mathcal{F}_{\sigma_m}^i)_{i=1}^3$ is a total foliation in tFol(I, n) and σ_m represents a half twist of m-th and (m + 1)-st strings. See Figure 8.

Figure 8. Proof of Lemma 3.12.

Let $(\mathcal{F}_{\rho_m}^i)_{i=1}^3$ and $(\mathcal{F}_{\tau_m}^i)_{i=1}^3$ be *n*-times compositions $(\mathcal{F}_m^i * \cdots * \mathcal{F}_m^i)_{i=1}^3$ and $(\mathscr{G}_m^i * \cdots * \mathscr{G}_m^i)_{i=1}^3$ respectively. Put $\rho_m = \sigma((\mathscr{F}_{\rho_m}^i)_{i=1}^3)$ and $\tau_m = \sigma((\mathscr{F}_{\tau_m}^i)_{i=1}^3)$. We can see that both $(\mathcal{F}_{\rho_m}^i)_{i=1}^3$ and $(\mathcal{F}_{\tau_m}^i)_{i=1}^3$ are total foliations in tFol(I,n) and ρ_m (resp. τ_m) is represented by a braid such that the m-th string winds once in the y-(resp. x-)direction and other strings are fixed.

It is easy to see that $\Theta_k((\mathcal{F}_{\sigma}^i)_{i=1}^3, j) = 0$ for any $k = 1, 2, m = 0, \ldots, n-1$, and $\sigma = \sigma_m, \rho_m, \tau_m$. It is known that $\{\sigma_m, \rho_m, \tau_m \mid m = 0, \ldots, n-1\}$ generates $\pi_0(B_n(I))$ (see e.g. [1] or [9]). Hence, we can obtain the required total foliation as a composition of the total foliations constructed above and their inverses.

Lemma 3.13. There exists $(\mathcal{F}_1^i)_{i=1}^3 \in \mathsf{tFol}(A_1,n)$ satisfying

$$\Theta_1((\mathcal{F}_1^i)_{i=1}^3, j) = 1/8, \quad \Theta_2((\mathcal{F}_1^i)_{i=1}^3, j) = 0$$
 (7)

for any j = 0, ..., n - 1.

Proof. Take a smooth map $\bar{\chi}_3$: $[0,1] \to \mathbb{R}$ such that

- $0 \le \frac{d\bar{\chi}_3}{dx}(x) \le \eta^{-1}$ holds for any $x \in [0,1]$,
- $\bar{\chi}_3(x) = 0$ holds for any $x \in [0, 1 (9/16n)]$, and $\bar{\chi}_3(x) = 1$ holds for any $x \in [1 (7/16n), 1]$.

It induces a map $\chi_3 \colon S^1 \to S^1$ of degree 1. We define a diffeomorphism G of W_0 by $G(t,x,y) = (t,x,y+\chi_3(x))$ if $t \in [3/4,1]$ and G(t,x,y) = (t,x,y) otherwise. It is well-defined and satisfies $G(\mathcal{F}^i_{\text{std}}|_{W_0}) = \mathcal{F}^i_{\text{std}}|_{W_0}$ for i=2,3. Since $G(\mathcal{F}^1_{\text{std}}|_{W_0})$ is almost horizontal, Proposition 3.5 implies that there exists an extension \mathcal{G} of $G(\mathcal{F}^1_{\text{std}}|_{W_0})$ to W which is transverse to $\mathcal{F}^2_{\text{std}}$ and $\mathcal{F}^3_{\text{std}}$. Remark that the constant braid Γ_0 is tangent to $\mathcal{G} \cap \mathcal{F}^2_{\text{std}}$.

Since $\chi_3(x)-x$ is a map of degree 0, we can take a smooth function α on $S^1\times [0,1]$ such that $\alpha(x,t)=0$ for $(x,t)\in S^1\times [0,3/4]$ and $x=\chi_3(x)+\alpha(x,t)$ for $(x,t)\in S^1\times [7/8,1]$. We define a diffeomorphism \overline{G} of W by $\overline{G}(t,x,y)=(t,x,y+\alpha(x,t))$. Remark that $\overline{G}\circ G(t,x,y)=(t,x,y)$ if $t\in [0,3/4]$ and $\overline{G}\circ G(t,x,y)=(t,A_1(x,y))$ if $t\in [7/8,1]$. Put $\mathcal{F}_1^1=\overline{G}(\mathcal{G}),\,\mathcal{F}_1^i=\overline{G}(\mathcal{F}_{std}^i)$ for i=2,3 and $\Gamma=\overline{G}(\Gamma_0)$. Then, $(\mathcal{F}_1^i)_{i=1}^3$ is a total foliation contained in F(I) and $\overline{G}(\Gamma_0)$ is a braid in F(I) which is tangent to F(I). Therefore, F(I) an element of F(I) is a braid in F(I) for any F(I) salmost horizontal on F(I) and F(I) we also have F(I) for any F(I) for any F(I) and F(I) we also have F(I) for any F(I) for any F(I) for any F(I) and F(I) we also have F(I) for any F(I) for an

Starting from the total foliation $(\mathcal{F}_1^i)_{i=1}^3$ in Lemma 3.13, we define a total foliation $(\mathcal{F}_2^i)_{i=1}^3$ by $\mathcal{F}_2^1 = F_{A_{xy}}(\mathcal{F}_1^2)$, $\mathcal{F}_2^2 = F_{A_{xy}}(\mathcal{F}_1^1)$ and $\mathcal{F}_2^3 = F_{A_{xy}}(\mathcal{F}_1^3)$. By Lemma 3.10 and the third equation of (6), we have $(\mathcal{F}_2^i)_{i=1}^3 \in \text{tFol}(A_2)$. By (7), we also have

$$\Theta_1((\mathcal{F}_2^i)_{i=1}^3, j) = 0, \quad \Theta_2((\mathcal{F}_2^i)_{i=1}^3, j) = -1/8.$$
 (8)

for any j = 0, ..., n - 1.

Figure 9. Proof of Lemma 3.13.

Lemma 3.14. For any $m \in \mathbb{Z}$, there exists $(\mathcal{F}^i)_{i=1}^3 \in tFol(I, n)$ such that

$$\Theta_1((\mathcal{F}^i)_{i=1}^3, j) = \Theta_2((\mathcal{F}^i)_{i=1}^3, j) = m$$

for any j = 0, ..., n - 1.

Proof. Let $((\mathcal{F}_2^i)^{-1})_{i=1}^3$ be the inverse of $(\mathcal{F}_2^i)_{i=1}^3$. Put $\mathcal{G}^i = \mathcal{F}_1^i * (\mathcal{F}_2^i)^{-1}$ for i=1,2,3. Since $A_* = A_2^{-1} \cdot A_1$, we have $(\mathcal{G}^i)_{i=1}^3 \in \text{tFol}(A_*,n)$. The equations (7) and (8), we also have $\Theta_1((\mathcal{G}^i)_{i=1}^3,j) = 1/4$ and $\Theta_2((\mathcal{G}^i)_{i=1}^3,j) = 1/8$ for any $j=0,\ldots,n-1$. Let $(\mathcal{G}_k^i)_{i=1}^3$ be the k-times composition of $(\mathcal{G}^i)_{i=1}^3$. Since $A_*^3 = -I$, we have $\Theta_1((\mathcal{G}^i)_{3i=1}^3,j) = 1/2$ and $\Theta_2((\mathcal{G}^i)_{3i=1}^3,j) = 1/2$ for any $j=0,\ldots,n-1$. Hence, (6m)-times composition $(\mathcal{G}^i_{6m})_{i=1}^3$ of $(\mathcal{G}^i)_{i=1}^3$ is the required total foliation for $m\geq 0$. For m<0, it is sufficient to take the inverse $((\mathcal{G}^i)_{6m})^{-1})_{i=1}^3$ of $(\mathcal{G}^i)_{6m}^3$.

Lemma 3.15. For any $A \in SL(2,\mathbb{Z})$, there exist $(\mathcal{F}^i)_{i=1}^3 \in tFol(A,n)$ such that $\Theta_1((\mathcal{F}^i)_{i=1}^3,j)$ and $\Theta_2((\mathcal{F}^i)_{i=1}^3,j)$ does not depends on j.

Proof. It is an immediate consequence of Lemma 3.13 and the fact that $\{A_1, A_2\}$ generates $SL(2, \mathbb{Z})$.

Finally, Proposition 3.9 is an immediate consequence of Lemmas 3.11, 3.12, 3.14, and 3.15.

3.3. Braided knots in embedded solid tori. Let ψ be an embedding from $Z = S^1 \times D^2$ to an oriented three-dimensional manifold M. We say ψ is a 0-framed null-homotopic embedding if $K_0 = \psi(S^1 \times \{(0,0)\})$ is null-homotopic and ψ is a 0-framed tubular coordinate of K_0 . We also say ψ is unknotted if K_0 is unknotted.

We say a smooth link L in M is ψ -braided if $L \subset \psi(Z)$ and $\psi^{-1}(L)$ is transverse to the production foliation $\{t \times D^2\}_{t \in S^1}$. Remark that any component of L is a ψ -braided knot.

Definition 3.16. Let L be a ψ -braided oriented knot or link. We denote by $n(L; \psi)$ the cardinality of $\psi^{-1}(L) \cap (0 \times D^2)$. We define the (ψ, n) -framing of L in M by a vector field

$$v_n(\psi(t,w)) = D\psi(\cos(2\pi nt)e_x(t,w) + \sin(2\pi nt)e_y(t,w))$$

for $(t, w) \in \psi^{-1}(L)$, where (e_t, e_x, e_y) is the standard frame on $S^1 \times D^2 \subset S^1 \times \mathbb{R}^2$.

Remark that (ψ, n) -framing of K may not be the n-framing (in the sense of Definition 2.12) even if ψ is 0-framed and unknotted. See Lemma 3.18.

Let ψ_0 be a 0-framed unknotted embedding of Z into \mathbb{R}^3 defined by $\psi_0(t,x,y) = ((x+2)\cos 2\pi t, (x+2)\sin 2\pi t, y)$ and P_{xy} denote the projection from \mathbb{R}^3 to \mathbb{R}^2 given by $P_{xy}(x,y,z) = (x,y)$. For any given 0-framed unknotted embedding ψ of Z into M, we can take an embedding φ of \mathbb{R}^3 into M so that $\varphi^{-1} \circ \psi = \psi_0$. Take a ψ -braided link L in M. The map φ can be perturbed into another embedding φ_1 such that the map $P_{xy} \circ \varphi_1$ is a regular projection associated with $\varphi_1^{-1}(L)$. See e.g. [14] for the definition of a regular projection and a link diagram. For any component K of L, let $\omega_{\pm}(K;\psi)$ be the number of positive and negative crossings in the diagram $P_{xy} \circ \varphi_1^{-1}(K)$. See Figure 10. We put $\omega(K;\psi) = \omega_+(K;\psi) - \omega_-(K;\psi)$. Remark

Figure 10. A link diagram of a braided knot.

that $\omega(K; \psi)$ and $n(K; \psi)$ depend only on the isotopy class of K as a ψ -braided knot.

We show two lemmas, which give relations between $n(K; \psi)$, $\omega(K; \psi)$ and the framing of K.

Lemma 3.17. Let ψ be a 0-framed unknotted embedding from Z to M and K be a ψ -braided knot in M. Then, $\omega(K; \psi) + n(K; \psi)$ is odd.

Proof. Since K is connected, it induces a cyclic permutation on the $n(K; \psi)$ -points set $\psi^{-1}(K) \cap (0 \times D^2)$. Then, the signature of the permutation is $(-1)^{n(K;\psi)+1}$. Since the induced permutation is the product of $(\omega_+(K;\psi) + \omega_-(K;\psi))$ transpositions, its signature is also $(-1)^{(\omega_+(K;\psi)+\omega_-(K;\psi))}$. In particular, $n(K;\psi) - (\omega_+(K;\psi) + \omega_-(K;\psi))$ is odd. Hence, also $\omega(K;\psi) + n(K;\psi)$ is.

Lemma 3.18. Let ψ be a 0-framed unknotted embedding from Z to M and let K be a ψ -braided knot in M. Then, the (ψ, m) -framing of K coincides with the $(\omega(K; \psi) + m \cdot n(K; \psi))$ -framing of K as a null-homotopic knot in M.

Proof. Suppose that the $(\psi, 0)$ -framing of K is the n_0 -framing. It is easy to see that the (ψ, m) -framing is $n_0 + m \cdot n(K; \psi)$. Under the identification of $\psi(Z)$ and the standard torus $\psi_0(Z)$, the $(\psi, 0)$ -framing gives the *blackboard framing*, that is, the one transverse to the projection to the link diagram. By a well-known result in knot theory (see e.g. [8], Proposition 4.5.8), it coincides with the $\omega(K; \psi)$ -framing of K. Hence, we have $n_0 = \omega(K; \psi)$.

3.4. The trefoil complement. In this subsection, we construct a total foliation on S^3 containing \mathcal{R} -components such that their cores form an arbitrary given link. It will be done by using the fibration of the complement of the trefoil. Note that the same construction can be done for other fibered knot with one-punctured torus fibers, e.g. the figure-eight knot.

Let A_* be the matrix defined in (5) and M_* be the mapping torus $W/(0,w) \sim (1,A_*\cdot w)$ of the linear map defined by A_* . By P_{M_*} , we denote the natural projection from W to M_* . Since any total foliation $(\mathcal{F}^i)_{i=1}^3 \in \mathrm{tFol}(A_*)$ is compatible with the projection P_{M_*} at ∂W , we can define a total foliation $(P_{M_*}(\mathcal{F}^i))_{i=1}^3$ on M_* such that $P_{M_*}(\mathcal{F}^i)(P_{M_*}(t,w)) = P_{M_*}(\mathcal{F}^i(t,w))$ for any i=1,2,3 and $(t,w) \in W$.

Since $Q_0 = (0,0) + \mathbb{Z}^2$ is a fixed point of A_* , $P_{M_*}([0,1] \times Q_0)$ is a knot in M_* . We denote it by K_0 . Fix an embedding $\psi_{K_0} \colon Z \to M_*$ such that $\psi_{K_0}(S^1 \times \{(0,0)\}) = K_0$ and $\psi_{K_0}(t \times D^2) \subset P_{M_*}(t \times D^2(1/8n))$.

Proposition 3.19. For any ψ_{K_0} -braided link L and $m \in \mathbb{Z}$, there exists a total foliation $(\mathcal{F}^i)_{i=1}^3$ on M_* such that each component of L is the core of an \mathcal{R} -component and its framing determined by \mathcal{F}^1 is the (ψ_{K_0}, m) -framing.

Proof. We take a smooth function θ on [0,1] such that $D\psi(e_x(t,0,0))$ is parallel to $DP_{M_*}(\cos\theta(t)e_x(t,0,0)+\sin\theta(t)e_y(t,0,0))$. For $m\in\mathbb{Z}$, we define a vector field \bar{v}_m on W by

$$\bar{v}_m(t, w) = \cos(2\pi mt + \theta(t))e_x(t, w) + \sin(2\pi mt + \theta(t))e_y(t, w)$$

for $(t, w) \in W$. Then, the vector field $v_m = DP_{M_*}(\bar{v}_m)$ on M_* is well-defined and the restriction of v_m to a knot K in M_* gives the (ψ_{K_0}, m) -framing of K.

Now let $\{F_s\}_{s\in[0,1]}$ be an isotopy of M_* so that F_0 is the identity map, $F_1(L)\in B_n(A_*)$ for some $n\geq 1$, and $F_s(P_{M_*}(t\times\mathbb{T}^2))=P_{M_*}(t\times\mathbb{T}^2)$ for any $s\in[0,1]$ and $t\in S^1$. Put $L'=F_1(L)$. Since $\{(F_s(L),v_m)\}_{s\in[0,1]}$ is an isotopy between framed knots (L,v_m) and (L',v_m) , it is sufficient to find a total foliation $(\mathcal{F}^i)_{i=1}^3$ such that each component of L' is the core of an \mathcal{R} -component and its framing determined by \mathcal{F}^1 coincides with the one represented by v_m .

Take a subset S_L of $\{0,\ldots,n-1\}$ such that each component of L' contains exactly one point of $\{P_{M_*}(0,Q_j)\mid j\in S_L\}$. By $H_{\mathcal{R}}\colon\mathbb{R}\to\mathbb{R}$, we denote the holonomy map of the foliation $\widehat{\mathcal{R}}^1$ (see Subsection 2.2 for the definition of $\widehat{\mathcal{R}}^1$). Proposition 3.9 implies that there exist $n\geq 1$, $\delta>0$, and $(\mathcal{G}^i)_{i=1}^3\in \mathrm{tFol}(A_*,n)$ which satisfy the following properties:

- $P_{M_*}^{-1}(L')$ is tangent to $\mathcal{G}^1 \cap \mathcal{G}^2$,
- $\Theta_1((\mathcal{G}^i)_{i=1}^3, j) = m + \theta(1)$ for any j = 0, ..., n-1, and
- both $H_x^\delta((\mathcal{G}^i)_{i=1}^3,j)$ and $H_y^\delta((\mathcal{G}^i)_{i=1}^3,j)$ are conjugate to $H_{\mathcal{R}}|_{[-2,2]}$ for $j\in S_L$ and the identity map otherwise.

The total foliation $(\mathcal{G}^i)_{i=1}^3$ induces a total foliation $(\mathcal{F}_*^i = P_{M_*}(\mathcal{G}^i))_{i=1}^3$ on M_* . For each component K' of L', the first and the last condition above imply that there exists an embedding $\psi_{K'} \colon Z \to M_*$ such that $\psi_{K'}(S^1 \times \{(0,0)\}) = K'$ and $\psi_{K'}(\mathcal{R}^i) = \mathcal{G}^i|_{\psi_{K'}(Z)}$. Since \mathcal{G}^3 is transverse to $(\mathcal{G}^1 \cap \mathcal{G}^2)$, $\mathcal{F}_*^3|_{\psi_{K'}(Z)}$ is diffeomorphic to the product foliation $\{t \times D^2 \mid t \in S^1\}$. Hence, a turbularization of \mathcal{F}_*^3 at $\psi_{K'}(Z)$ produces an \mathcal{R} -component whose core is K'.

By the second condition in the above, the framing on L' determined by \mathcal{F}^1_* coincides with the one represented by v_m . Hence, we can obtain the required total foliation by a turbularization along a tubular neighborhood of L'.

Let K^3 be the right-handed trefoil on S^3 . It is known that K^3 is a fibered knot with monodromy matrix A_* (see e.g. Section 10.I in [14]). Hence, there exists a diffeomorphism φ from $M_* \setminus K_0$ to $S^3 \setminus K^3$, an embedding ψ_{K^3} from Z to S^3 , and an integer m_* such that $\psi_{K^3}(S^1 \times \{(0,0)\}) = K^3$ and

$$\varphi \circ \psi_{K_0}(t, r\cos(2\pi\theta), r\sin(2\pi\theta))) = \psi_{K^3}(\theta + m_*t, r\cos(2\pi t), r\sin(2\pi t)).$$
 (9)

for any $t, \theta \in S^1$ and $r \in [0, 1]$. Note that ψ_{K^3} is a 0-framed null-homotopic embedding as $\psi_{K^3}(S^1 \times \{(1, 0)\})$ is contained in a Seifert surface $\varphi(P_{M_*}(0 \times \{\mathbb{T}^2 \setminus Q_0\}))$ of K^3 . We define another embedding ψ_0 from Z to S^3 by

$$\psi_0(t, x, y) = \psi_{K^3}\left(\frac{x}{4}, \frac{y+2}{4}\cos(2\pi t), \frac{y+2}{4}\sin(2\pi t)\right).$$

Then, the core $\psi_0(S^1 \times \{(0,0)\})$ bounds a disk $D_0 = \psi_{K^3}(0 \times D^2(1/2))$. In particular, $\psi_0(S^1 \times \{(0,0)\})$ is a meridian of K^3 . Since $\psi_0(S^1 \times \{(0,-1)\})$ is contained in D_0 , ψ_0 is a 0-framed unknotted embedding. See Figure 11.

Figure 11. The 0-framed unknotted embedding ψ_0 .

Lemma 3.20. For any ψ_0 -braided link L, $L' = \varphi^{-1}(L)$ is ψ_{K_0} -braided and φ maps the $(\psi_0, n - m_*)$ -framing of L' to the (ψ_{K_0}, n) -framing of L.

Proof. By direct calculation, we have

$$\psi_0(t,x,y) = \varphi \circ \psi_{K_0}\left(t,\frac{y+2}{4}\cos 2\pi\left(\frac{x}{4} - m_*t\right),\frac{y+2}{4}\sin 2\pi\left(\frac{x}{4} - m_*t\right)\right)$$

for $(t, x, y) \in Z$. It implies $\varphi^{-1} \circ \psi_0(t \times D^2) \subset \psi_{K_0}(t \times D^2)$ for any $t \in S^1$. Hence, $L' = \varphi^{-1}(L)$ is ψ_{K_0} -braided for any ψ_0 -braided link L. The above equation also implies that φ^{-1} maps the $(\psi_0, 0)$ -framing of L to the $(\psi_{K_0}, -m_*)$ -framing of L'. Since the map $\psi_{K_0}^{-1} \circ \varphi^{-1} \circ \psi_0$ preserves the orientation of $t \times D^2$, it implies that the φ^{-1} maps the (ψ_0, n) -framing of L to the $(\psi_{K_0}, n - m_*)$ -framing of L'. \square

Proposition 3.21. For any ψ_0 -braided link L, there exists a total foliation $(\mathcal{F}^i)_{i=1}^3$ on S^3 such that any connected component K of L is the core of an $(\omega(K;\psi_0) + n(K;\psi_0))$ -framed \mathcal{R} -component.

Proof. The link $L_* = K_0 \cup \varphi^{-1}(L)$ in M_* is ψ_{K_0} -braided. By Proposition 3.19, there exists a total foliation $(\mathcal{F}_*^i)_{i=1}^3$ on M_* such that each component of L_* is the core of an \mathcal{R} -component and the framing determined by \mathcal{F}_*^1 coincides with the $(\psi_{K_0}, 1-m_*)$ -framing. Let R_0 be the \mathcal{R} component of $(\mathcal{F}_*^i)_{i=1}^3$ whose core is K_0 . Without loss of generality, we may assume that $R_0 = \psi_{K_0}(S^1 \times D^2(\epsilon))$ for some $\epsilon > 0$. Then, $a_{\mathcal{R}}(R_0)$ is represented by a curve

$$C_0 = \psi_{K_0}(\{(t, \epsilon \cos(2\pi(1 - m_*)t), \epsilon \sin(2\pi(1 - m_*)t)) \mid t \in S^1\})$$

with a suitable orientation.

Put $\mathscr{F}^i = \varphi(\mathscr{F}^i_*|_{\overline{M_* \setminus R}})$ for i = 1, 2, 3 and $R'_0 = \psi_{K^3}(S^1 \times D^2(\epsilon))$. Then, $(\mathscr{F}^i)_{i=1}^3$ is a total foliation on $\overline{S^3 \setminus R'_0}$ with an \mathscr{R} -boundary $\partial R'_0$. By (9), we have

$$\varphi(C_0) = \psi_{K^3}(\{(t, \epsilon \cos(2\pi t), \epsilon \sin(2\pi t))\}).$$

Since ψ_{K^3} is a 0-framed embedding, we can extend $(\mathcal{F}^i)_{i=1}^3$ so that R'_0 is a (+1)-framed \mathcal{R} -component with $C(R_0)=K^3$. Since the framing on L_* determined by \mathcal{F}^1_* coincides with the $(\psi_{K_0}, 1-m_*)$ -framing, Lemma 3.20 implies that the framing on L determined by \mathcal{F}^1 is the $(\psi_0, 1)$ -framing. Since ψ_0 is a 0-framed unknotted embedding, it gives the $(\omega(K;\psi_0)+n(K;\psi_0))$ -framing on each component K of L by Lemma 3.18. In particular, each component K of L is the core of an $(\omega(K;\psi_0)+n(K;\psi_0))$ -framed \mathcal{R} -component.

3.5. A proof of Hardorp's theorem. First, we show that we can change the framing of an \mathcal{R} -component by an arbitrary even integer.

Lemma 3.22. Suppose that a total foliation $(\mathcal{F}^i)_{i=1}^3$ on S^3 admits a k-framed \mathcal{R} -component R. Then, for any integer n, there exists a total foliation $(\mathcal{F}_n^i)_{i=1}^3$ on S^3 such that it admits a (k+2n)-framed \mathcal{R} -component R' with C(R')=C(R) and $\mathcal{F}_n^i|_{\overline{S^3\setminus R}}=\mathcal{F}^i|_{\overline{S^3\setminus R}}$ for i=1,2,3.

Proof. Let ψ be a 0-framed unknotted embedding of Z into S^3 and $L = K_1 \cup K_2$ be the ψ -braided link in Figure 12. By Proposition 3.21, we can take a total foliation $(\mathcal{E}^i)_{i=1}^3$ on S^3 which admits \mathcal{R} -components R_1 and R_2 such that K_i is the core of

Figure 12. The link L for the proof of Lemma 3.22.

 R_i for i=1,2 and the framings of R_1 and R_2 are +3 and +1, respectively. Put $M_+=\overline{S^3}\setminus R_2$. Since L is a positive Hopf link, M_+ is diffeomorphic to Z. Hence, there exists a diffeomorphism $\varphi_+\colon Z\to M_+$ such that $K_1=\varphi_+(S^1\times\{(0,0)\})$ coincides with the core of R_1 as oriented knots and $(\varphi_+|_{\partial Z})_*(a_t)=a_{\mathcal{R}}(\partial R_2)$, where a_t is the homology class in $H_1(\partial Z,\mathbb{Z})$ represented by a map $t\mapsto (t,1,0)$. It is easy to see that K_1 is a φ_+ -braided knot. Since K_1 is (+3)-framed and K_2 is (+1)-framed, \mathcal{G}_*^1 gives the $(\varphi_+,2)$ -framing of K_1 .

The lemma for n=0 is trivial. First, we show the lemma for n=1. Let $\psi\colon Z\to R$ be a diffeomorphism such that $\psi(S^1\times\{(0,0)\})=C(R)$ as oriented knots and $\psi_*(a_t)=a_{\mathcal{R}}(\partial R)$. By Proposition 2.11, if we choose φ_+ suitably in its isotopy class, then we can obtain a total foliation $(\mathcal{F}_1^i)_{i=1}^3$ on S^3 such that $\mathcal{F}_1^i|_R=\psi\circ\varphi_+^{-1}(\mathcal{G}_*^i|_{M_+})$ and $\mathcal{F}_1^i|_{\overline{S^3\setminus R}}=\mathcal{F}^i|_{\overline{S^3\setminus R}}$ for i=1,2,3. Since ψ is a k-framed embedding and \mathcal{G}_*^1 gives the $(\varphi_+,2)$ -framing of $C(R_1)=K_1,\ \psi\circ\varphi_+^{-1}(R_1)$ is a (k+2)-framed \mathcal{R} -component with $C(\psi\circ\varphi_+^{-1}(R_1))=C(R)$. By inductive construction, it gives the proof for $n\geq 1$.

Using the fact that $M_- = \overline{S^3 \setminus R_1}$ is diffeomorphic to Z, we can take a diffeomorphism $\varphi_- \colon M_+ \to Z$ such that $\varphi_-(K_2) = S^1 \times \{(0,0)\}$ as oriented knots and $(\varphi_-)_*(a_{\mathcal{R}}(\partial R_2)) = a_t$. Similar to φ_+ , K_2 is ψ_- -braided and \mathcal{G}^1_* gives the $(\varphi_-, -2)$ -framing of K_2 . Hence, the same construction to the above completes the proof for $n \le -1$.

Now, we give an alternative proof of Hardorp's theorem [10] with some extension.

Theorem 3.23. For any given closed three-dimensional manifold M equipped with a spin structure s, there exists a total foliation $(\mathcal{F}^i)_{i=1}^3$ such that

- s is the spin structure given by $(\mathcal{F}^i)_{i=1}^3$,
- $(\mathcal{F}^i)_{i=1}^3$ admits two unknotted \mathcal{R} -components R_+ and R_- ,
- R_+ is (+1)-framed and R_- is (-1)-framed, and
- R_+ and R_- are contained in mutually disjoint three-dimensional balls.

Proof. Let X be a four-dimensional 2-handlebody such that $\partial X = M$ and the restriction of the unique spin structure on X to M is s. Let L_0 be the Kirby diagram of X. We denote by n(K) the integer-valued framing of each component K of L_0 . Remark that all n(K) are even since X admits a spin structure. Take two unknots K_- and K_+ which are contained in mutually disjoint three-dimensional ball in $S^3 \setminus L_0$. Put $n(K_-) = 0$ and $n(K_+) = 2$.

Fix an unknotted embedding ψ_0 of the solid torus. Recall that any link can be ψ_0 -braided by Alexander's theorem (see *e.g.* [2], Theorem 2.1). By Proposition 3.21, there exists a total foliation $(\mathcal{F}_0^i)_{i=1}^3$ on S^3 such that each component K of $L_0 \cup K_- \cup K_+$ is contained in an \mathcal{R} -component with $(\omega(K;\psi_0) + n(K;\psi_0))$ -framing. Lemma 3.17 implies that these \mathcal{R} -components are odd-framed. By Lemma 3.22, we

can modify $(\mathcal{F}_0^i)_{i=1}^3$ so that the framing of an \mathcal{R} -component R is n(C(R))-1. Then, the standard surgery on L_0 (not $L_0 \cup K_- \cup K_+$) produces a total foliation $(\mathcal{F}^i)_{i=1}^3$ on M. It is easy to see that each $K_\pm \subset M$ is the core of a (± 1) -framed unknotted \mathcal{R} -component of $(\mathcal{F}^i)_{i=1}^3$. Proposition 2.14 implies that the spin structure given by $(\mathcal{F}^i)_{i=1}^3$ is s.

Remark The last sentence of Paragraph 14 of Chapter 7 (p. 71) of [10] seems incorrect. In fact, branched double covering along the unknot changes the framing of braided knots in general. For example, Figure 13 illustrates a branched double

Figure 13. Double covering of a solid torus.

covering along the unknot K_* . The box represents a tangle where the difference of the numbers of positive and negative crossings is k. Suppose that the knot K in the left-side of the figure has the blackboard framing, which is equal to the (k+1)-framing. In the right-side of the figure, which is a double covering of the left-side, the lift K' of the framed knot K has the blackboard framing, which is equal to the k-framing. Hence, the knot K is isotopic to K' as a knot, but is not isotopic to K' as a framed knot. It is because one positive crossing in the left-side is not counted in the right-side. The same phenomenon occurs in the setting in Chapter 7 of [10].

3.6. Proof of Theorem 1.1. First, we construct a suitable total foliation on S^3 . Let $(\mathcal{R}^i_+)^3_{i=1}$ be the positive total Reeb foliation on S^3 , that is, a total foliation consisting of two (-1)-framed unknotted \mathcal{R} -components.

Lemma 3.24. For any integer n, there exists a total foliation $(\mathcal{G}_n^i)_{i=1}^3$ on S^3 with unknotted \mathcal{R} -components R_+ and R_- such that $H((\mathcal{G}_n^i)_{i=1}^3, (\mathcal{R}_+^i)_{i=1}^3) = n$, R_+ is (+1)-framed, R_- is (-1)-framed, and R_+ and R_- are contained in mutually disjoint three-dimensional balls.

Proof. First, we show the lemma for n = -1. By Theorem 3.23, there exists a total foliation $(\mathcal{F}_0^i)_{i=1}^3$ on S^3 with unknotted \mathcal{R} -components R_+ and R_- such that

 R_+ is (+1)-framed, R_- is (-1)-framed, and they are contained in mutually disjoint three-dimensional balls B_+ and B_- , respectively. Since $\overline{S^3 \setminus R_+}$ is an unknotted solid torus, we can take an *orientation reversing* diffeomorphism φ on S^3 so that $\varphi(\overline{S^3 \setminus R_+}) = R_+$. Then, $\overline{S^3 \setminus R_+} = \varphi(R_+)$ is a (-1)-framed unknotted \mathcal{R} -component of $(\varphi(\mathcal{F}_0^i))_{i=1}^3$.

Let $(\mathcal{G}_{-1}^i)_{i=1}^3$ be the total foliation obtained by gluing $(\mathcal{F}_0^i)_{i=1}^3$ and $(\varphi(\mathcal{F}_0^i))_{i=1}^3$ along \mathcal{R} -components R_+ and $\varphi(R_+)$ as in Subsection 2.4. It admits unknotted \mathcal{R} -components R_- and $\varphi(R_-)$ which are contained in mutually disjoint balls B_- and $\varphi(B_-) \subset \varphi(S^3 \setminus R_+) = R_+$. Then, we have

$$\begin{split} H((\mathcal{G}_{-1}^{i})_{i=1}^{3}, (\mathcal{R}_{+}^{i})_{i=1}^{3}) &= H((\mathcal{G}_{-1}^{i})_{i=1}^{3}, (\mathcal{F}^{i})_{i=1}^{3}) + H((\mathcal{F}^{i})_{i=1}^{3}, (\mathcal{R}_{+}^{i})_{i=1}^{3}) \\ &= H((\varphi(\mathcal{F}^{i}))_{i=1}^{3}, (\mathcal{R}_{+}^{i})_{i=1}^{3}) + H((\mathcal{F}^{i})_{i=1}^{3}, (\mathcal{R}_{+}^{i})_{i=1}^{3}) \\ &= -1. \end{split}$$

where each equality follows from the formulas (2), (3), and (4) in Subsections 2.1 and 2.3. Since R_- and $\varphi(R_-)$ have the (-1) and (+1)-framings respectively, the proof for n=-1 is completed.

Second, we show the lemma for $n \leq -1$ by induction. Suppose that there exists a total foliation $(\mathcal{G}_n^i)_{i=1}^3$ which satisfies the assertion of the lemma for some $n \leq -1$. Let R'_+ and R'_- be (+1) and (-1)-framed unknotted \mathcal{R} -components contained in mutually disjoint balls. We construct the total foliation $(\mathcal{G}_{n-1}^i)_{i=1}^3$ by gluing $(\mathcal{G}_n^i)_{i=1}^3$ and $(\mathcal{G}_{n-1}^i)_{i=1}^3$ along \mathcal{R} -components R'_+ and R_- . By the formula (4), we have $H((\mathcal{G}_{n-1}^i)_{i=1}^3, (\mathcal{R}_+^i)_{i=1}^3) = n-1$. It is easy to see that \mathcal{R} -components R'_- and $\varphi(R_-)$ satisfy the assertion of the lemma.

For $n \geq 0$, put $(\mathcal{G}_n^i)_{i=1}^3 = (\varphi(\mathcal{G}_{-n-1}^i))_{i=1}^3$. By the formula (3), we have $H((\mathcal{G}_n^i)_{i=1}^3, (\mathcal{R}_+^i)_{i=1}^3) = n$. It is easy to see that $(\mathcal{G}_n^i)_{i=1}^3$ is the required one. \square

Now, we show the following theorem which implies Theorem 1.1.

Theorem 3.25. Let M be a closed oriented three-dimensional manifold. Any homotopy class of total plane fields on M can be realized by a total foliation $(\mathcal{F}^i)_{i=1}^3$ with (+1)- and (-1)-framed unknotted \mathcal{R} -components.

Proof. Fix a spin structure s on M. By Theorem 3.23, we can take a total foliation $(\mathcal{F}^i)_{i=1}^3$ on M such that it admits (+1) and (-1)-framed unknotted \mathcal{R} -components R_+ and R_- , and the spin structure given by $(\mathcal{F}^i)_{i=1}^3$ is s. By Proposition 2.5, it is sufficient to show that there exists a total foliation $(\mathcal{F}_n^i)_{i=1}^3$ on M such that it admits (+1)- and (-1)-unknotted \mathcal{R} -components, the spin structure given by $(\mathcal{F}_n^i)_{i=1}^3$ is s, and $H((\mathcal{F}_n^i)_{i=1}^3, (\mathcal{F}^i)_{i=1}^3) = n$ for any given integer n.

and $H((\mathcal{F}_n^i)_{i=1}^3, (\mathcal{F}^i)_{i=1}^3) = n$ for any given integer n.

Take an integer n. Let $(\mathcal{F}_n^i)_{i=1}^3$ be the total foliation on S^3 obtained in Lemma 3.24 for n. It admits (+1)-and (-1)-framed \mathcal{R} -components R'_+ and R'_- which are contained in mutually disjoint balls. Let $(\mathcal{F}_n^i)_{i=1}^3$ be the total foliation obtained by gluing

 $(\mathcal{F}^i)_{i=1}^3$ and $(\mathcal{G}_n^i)_{i=1}^3$ along \mathcal{R} -components R_+ and R'_- . Since R_+ is contained in a three-dimensional ball, $(\mathcal{F}_n^i)_{i=1}^3$ and $(\mathcal{F}^i)_{i=1}^3$ give the same spin structure. By Proposition 2.16, we obtain $H((\mathcal{F}_n^i)_{i=1}^3, (\mathcal{F}^i)_{i=1}^3) = n$. It is easy to see that R_- and R'_+ are (-1) and (+1)-framed unknotted \mathcal{R} -components of $(\mathcal{F}_n^i)_{i=1}^3$. \square

4. Bi-contact structures

First, we recall some basic definitions and results on contact topology. A plane field ξ on a three-dimensional manifold M is called a *positive* (resp. *negative*) *contact* structure if it is the kernel of a 1-form α with $\alpha \wedge d\alpha > 0$ (resp. $\alpha \wedge d\alpha < 0$). We say a knot K in (M, ξ) is Legendrian if it is tangent to ξ . The Thurston-Bennequin invariant $\operatorname{tb}(K, \xi)$ is the integer-valued framing of a null-homologous knot K given by ξ . The rotation $\operatorname{rot}(K, \xi)$ is the Euler number $\chi(\xi, \Sigma, K)$ of ξ on a Seifert surface Σ relative to K.

A contact structure ξ on M is called *overtwisted* if there exists a Legendrian unknot K such that $\mathrm{tb}(K,\xi)=0$. We say ξ is *tight* if it is not overtwisted. It is known that if ξ is tight, then any null-homologous Legendrian knot K satisfies the *Thurston–Bennequin inequality*:

$$\mathsf{tb}(K,\xi) + \chi(\Sigma) \leq -|\mathsf{rot}(K,\xi)|,$$

where $\chi(\Sigma)$ is the Euler number of a Seifert surface Σ of K.

Theorem 4.1 (Eliashberg, [6]). Let M be a three-dimensional closed manifold, any homotopy class of plane fields on M contains exactly one positive (resp. negative) overtwisted contact structure up to isotopy.

The following lemma gives a criterion for the overtwistedness of a contact structure which is close to a foliation of a total foliation.

Lemma 4.2. Let $(\mathcal{F}^i)_{i=1}^3$ be a total foliation on a three-dimensional manifold M and suppose it admits a (+1)-framed (resp. (-1)-framed) unknotted \mathcal{R} -component R. Then, any positive (resp. negative) contact structure which is sufficiently C^0 -close to $T\mathcal{F}^1$ is overtwisted.

Proof. We show the assertion for positive contact structures. The proof for negative contact structures is obtained by reversing the orientation.

The foliation $\mathcal{F}^1|_{\partial R}$ admits a closed leaf C which is isotopic to the core of R as an oriented knot in M. In particular, C is unknotted. The foliation \mathcal{F}^1 gives the (+1)-framing on C.

Recall that ∂R is a leaf of \mathcal{F}^3 . By Lemma 2.8, if a smooth plane field ξ is sufficiently C^0 -close to $T\mathcal{F}^1$, there exists a closed curve C_{ξ} in ∂R which is tangent

to $\xi \cap T\mathcal{F}^3$ and isotopic to C in ∂R . The curve C_{ξ} is unknotted in M, and hence, it bounds a disk D_{ξ} . Since $\xi \cap T\mathcal{F}^3$ gives an trivialization of ξ on D_{ξ} , we have $\operatorname{rot}(C_{\xi}, \xi) = 0$.

By the transversality, \mathcal{F}^1 and \mathcal{F}^3 define the same framing on C, and ξ and \mathcal{F}^3 define the same framing on C_{ξ} . Hence, the framing on C_{ξ} given by ξ is (+1). In particular, $\text{tb}(C_{\xi}, \xi) = +1$. It violates the Thurston-Bennequin inequality since

$$tb(C_{\xi}, \xi) + \chi(D_{\xi}) = 2 > 0 = |rot(C_{\xi}, \xi)|.$$

Now, we prove Theorem 1.5. Let M be a closed and oriented three-dimensional manifold. Fix a pair (ξ, η) of positive and negative contact structures such that they are homotopic as plane fields and their Euler class is zero. Then, there exists a total plane field $(\xi^i)_{i=1}^3$ on M such that ξ^i is homotopic to ξ and η for i=1,2,3. By Theorem 3.25, $(\xi_i)_{i=1}^3$ is homotopic to a total foliation $(\mathcal{F}^i)_{i=1}^3$ on M which admits (+1) and (-1)-framed unknotted \mathcal{R} -components.

By the fundamental theorem of confoliations ([7], Theorem 2.4.1) we can take a bi-contact structure (ξ_*, η_*) on M so that ξ_* is C^0 -sufficiently close to \mathcal{F}^1 and η_* is C^0 -sufficiently close to \mathcal{F}^2 . Lemma 4.2 implies that both ξ_* and η_* are overtwisted. By Theorem 4.1, ξ_* and η_* are isotopic to ξ and η as contact structures, respectively.
