Kleine Mitteilungen

On the Indirect Product of Subgroups

The following is a well-known property of external direct products¹⁾. If G is the external direct product of groups G_1, G_2, \dots, G_n , and H is a group such that $H = \times_{i=1}^k G_i$ for some $k < n$, then G is, up to isomorphism, the external direct product of H, G_{k+1}, \dots, G_n .

Recall that a group G is said to be the internal direct product of subgroups H_1, H_2, \dots, H_n if and only if each H_i is normal and each element g of G can be uniquely expressed (excluding order) in the form $g = h_1 h_2 \dots h_n$, where $h_i \in H_i$ for each i .

It is natural to ask the following question: If G is the internal direct product of subgroups H_1, H_2, \dots, H_n , what conditions can be placed on a subgroup H so that G is also the internal direct product of H, H_{k+1}, \dots, H_n for some $k < n$? I have been unable to find a text on group theory which considers this question.

For convenience let us first recall some basic results concerning direct products. A well-known characterization is that a group G is the internal direct product of subgroups H_1, H_2, \dots, H_n if and only if

$$\text{each } H_i \text{ is normal,} \tag{1}$$

$$G = \prod_{i=1}^n H_i, \text{ and} \tag{2}$$

$$H_j \cap \prod_{i \neq j} H_i = \{e\} \text{ for each } j. \tag{3}$$

Another characterization is that G is the internal direct product if and only if $\Phi: \times_{i=1}^n H_i \rightarrow G$, defined by $\Phi(h_1, h_2, \dots, h_n) = h_1 h_2 \dots h_n$, is an isomorphism.

Returning to the question, one might first guess that if $H \simeq \prod_{i=1}^k H_i$ for some $k < n$ ($\prod_{i=1}^k H_i$ is a subgroup since each H_i is normal and $H_i \cap \prod_{i \neq j} H_j = \{e\}$), then G will be the internal direct product of H, H_{k+1}, \dots, H_n since $G \simeq \times_{i=1}^n H_i, H \simeq \times_{i=1}^k H_i$, and G will thus be isomorphic to the external direct product of H, H_{k+1}, \dots, H_n . However, the special map Φ may not be an isomorphism. Consider $Z_2 \times Z_2$, and let $H_1 = Z_2 \times \{[0]\}, H_2 = \{[0]\} \times Z_2$, and $H = H_2$. Then $Z_2 \times Z_2$ is the internal direct product of H_1 and H_2 , and $H \simeq H_1$, but even though $Z_2 \times Z_2 \simeq H \times H_2, Z_2 \times Z_2$ is not the internal direct product of H and H_2 since $H + H_2 \neq Z_2 \times Z_2$.

This example also shows that requiring H to be normal in G , in addition to

¹⁾ External direct product means the same as "ordinary" direct product as indicated by the symbol

$$\times_{i=1}^n G_i.$$

being isomorphic to $\prod_{i=1}^k H_i$, does not suffice. But in the example just cited, note that

$H \cap H_2 \neq \{([0], [0])\}$. Thus, in addition to supposing H to be isomorphic to $\prod_{i=1}^k H_i$, let

us assume that $H \cap \prod_{i=k+1}^n H_i = \{e\}$. But consider $Z_2 \times S_3$, and let $H_1 = Z_2 \times \{\varepsilon\}$,

$H_2 = \{[0]\} \times S_3$, and $H = \{([0], \varepsilon), ([1], a)\}$, where $\varepsilon = \begin{pmatrix} 1 & 2 & 3 \\ 1 & 2 & 3 \end{pmatrix}$ and $a = \begin{pmatrix} 1 & 2 & 3 \\ 2 & 1 & 3 \end{pmatrix}$.

Then $Z_2 \times S_3$ is the internal direct product of H_1 and H_2 , $H \simeq H_1$, and $H \cap H_2 = \{([0], \varepsilon)\}$, but $Z_2 \times S_3$ is not the internal direct product of H and H_2 since H is not normal.

If we restrict ourselves to finite groups, we have the following.

Theorem: Let G be a finite group such that G is the internal direct product of subgroups H_1, H_2, \dots, H_n . If H is a normal subgroup such that $H \simeq \prod_{i=1}^k H_i$ for some

$k < n$ and $H \cap \prod_{i=k+1}^n H_i = \{e\}$, then G is the internal direct product of H, H_{k+1}, \dots, H_n .

Proof: It suffices to show that $\Phi: H \times H_{k+1} \times \dots \times H_n \rightarrow G$, defined by $\Phi(h, h_{k+1}, \dots, h_n) = hh_{k+1} \dots h_n$, is an isomorphism.

If K_1 and K_2 are normal subgroups and $K_1 \cap K_2 = \{e\}$, then the elements of K_1 commute with those of K_2 . Using this, the proof that Φ is a homomorphism is straightforward.

If $\Phi(a, a_{k+1}, \dots, a_n) = \Phi(b, b_{k+1}, \dots, b_n)$, then $aa_{k+1} \dots a_n = bb_{k+1} \dots b_n$. Hence $b^{-1}a = (b_{k+1} \dots b_n)(a_{k+1} \dots a_n)^{-1}$. Thus $b^{-1}a \in H \cap \prod_{i=k+1}^n H_i$, and $a = b$.

Continuing in the same manner, $a_i = b_i$ for $i = k+1, \dots, n$. Thus Φ is one-to-one.

Since $H \simeq \prod_{i=1}^k H_i$, the orders of $H \times H_{k+1} \times \dots \times H_n$ and of G are equal. Thus it follows that Φ is also onto. Therefore, Φ is an isomorphism.

I have answered the question for finite groups only. If G is infinite, the same conditions imposed on H are not sufficient to obtain the same result. Consider $Z \times Z$, and let $H_1 = Z \times \{0\}$, $H_2 = \{0\} \times Z$, and H be the subgroup generated by $(2, 0)$. Then $Z \times Z$ is the internal direct product of H_1 and H_2 , H is a normal subgroup such that $H \simeq H_1$ and $H \cap H_2 = \{(0, 0)\}$, but $Z \times Z$ is not the internal direct product of H and H_2 since $H + H_2 \neq Z \times Z$.
