## 4. THE NUMBER OF ZEROS.

**THEOREM 2.** For  $n \geq 1$  let  $z_{k,n}$  be the probability that exactly  $k$  among the  $n$  partial sums  $S_1, \dots, S_n$  vanish. For  $n = 0$  put

$$(4.1) \quad z_{0,0} = 1, \quad z_{1,0} = z_{2,0} = \dots = 0.$$

Then

$$(4.2) \quad z_{k,2n} = \frac{2^k}{2^{2n}} \binom{2n-k}{n}.$$

*Proof.* By definition

$$(4.3) \quad z_{0,2n} = p_{2n} = u_{2n}, \quad (n \geq 0).$$

To evaluate  $z_{1,2n}$  denote by  $B_r$  the event that among the partial sums  $S_1, \dots, S_{2n}$  exactly one vanishes and its index equals  $2r$ . Then for  $r < n$

$$\begin{aligned} B_r &= \{S_1 \neq 0, \dots, S_{2r-1} \neq 0, S_{2r} = 0, S_{2r+1} \neq 0, \dots, S_{2n} \neq 0\} \\ &\equiv \{S_1 \neq 0, \dots, S_{2r-1} \neq 0, S_{2r} = 0\} \cap \{S_{2r+1} - S_{2r} \neq 0, \dots, S_{2n} - S_{2r} \neq 0\}. \end{aligned}$$

Since the two events on the right are stochastically independent and the  $B_r$  are mutually exclusive we conclude that

$$(4.5) \quad z_{1,2n} = \sum_{r=1}^n P\{B_r\} = \sum_{r=1}^n f_{2r} z_{0,2n-2r}.$$

Now by Theorem 1 the last event on the right in (4.4) has the same probability as the event  $\{S_{2n} - S_{2r} = 0\}$  and hence we have for  $r \leq n$

$$(4.6) \quad P\{B_r\} = P\{S_1 \neq 0, \dots, S_{2r-1} \neq 0, S_{2r} = 0, S_{2n} = 0\}.$$

The events appearing on the right side are mutually exclusive and their union is the event  $\{S_{2n} = 0\}$ ; hence

$$(4.7) \quad \sum_{r=1}^n P\{B_r\} = P\{S_{2n} = 0\} = u_{2n}.$$

Comparing (4.5) and (4.7) we see that

$$(4.8) \quad z_{1,2n} = u_{2n} = z_{0,2n} \quad \text{for } n \geq 1.$$

In like manner we can calculate  $z_{2,2n}, z_{3,2n}, \dots$  from the recursion formula

$$(4.9) \quad z_{k,2n} = \sum_{r=1}^{n-1} f_{2r} z_{k-1,2n-2r}, \quad k \geq 2, \quad n \geq 1.$$

which is proved exactly as (4.5). For  $k \geq 2$  the right side differs from the right side in (4.5) only in that the term  $r = n$  is absent, and therefore

$$(4.10) \quad z_{k,2n} = z_{1,2n} - f_{2n} = 2z_{1,2n} - z_{0,2n-2}, \quad n \geq 1.$$

From the last two relations we see directly by induction that *for  $k \geq 2$  and  $n \geq 1$  we have the recursion formula*

$$(4.11) \quad z_{k,2n} = 2z_{k-1,2n} - z_{k-2,2n-2}$$

If we write  $z_{k,2n} = 2^{k-2n} a_{k,2n}$  then (4.11) reduces to

$$(4.12) \quad a_{k-1,2n} = a_{k,2n} + a_{k-2,2n-2}$$

which is the well-known addition relation for binomial coefficients, and thus (4.2) holds.

This theorem has the following surprising

COROLLARY. *For each  $n \geq 1$  we have*

$$(4.13) \quad z_{0,2n} = z_{1,2n} > z_{2,2n} > z_{3,2n} > \dots > z_{n,2n}$$

Thus, independently of the number  $n$  of steps, the *most probable number of zeros is 0*, and the smaller the number, the more probable it is.

## 5. THE NUMBER OF CHANGES OF SIGN.

We say that in the sequence  $S_1, \dots, S_{2n}$  a *change of sign occurs at the place  $j$*  if  $S_{j-1}$  and  $S_{j+1}$  are of opposite signs. This requires that  $S_j = 0$ , and so  $j$  must be even. Given the first  $2n$  terms
