This supplement covers differential operators, for example, which usually are not continuous but have a continuous inverse. For such differential operators which have a derivative satisfying the assumptions $a$ ) and $b^{\prime}$ ) or $b^{\prime \prime}$ ) the existence of an $\Omega$-neighborhood can only fail at a " point " $(T, u)$ where $T_{(u)}^{\prime-1}$ doès not exist as a bounded linear operator. But the existence of a bounded inverse $T_{(u)}^{\prime-1}$ for each $u \in B_{1}, T$ being defined everywhere in $B_{1}$, is not sufficient to insure that $T$ has an inverse nor that the equation $T u=w$ is solvable for all $\mathfrak{w} \in B_{2}$.

## 8. On the differentiability of the solution.

In virtue of Theorem 7.1 and supplements the equation $T u=\theta$ is equivalent to $u=u(T)$ in an $\Omega$-neighborhood of $\left(T_{0}, u_{0}\right)$ under the above conditions or, in other words, $u(T)$ is a unique function of $T$ defined in $\Omega$ by $T u=\theta$. The conditions yield also the continuity of $u(T)$ in the sense that $u(T)$ tends to $u_{0}$ as $\left\|T u_{0}\right\| \rightarrow 0$ or, more precisely, $\left\|u(T)-u\left(T_{0}\right)\right\| \leqq C\left\|T u_{0}\right\|$ for some constant C. Therefore,

$$
\begin{equation*}
g(u)=\circ\left(\left\|u-u_{0}\right\|\right) \text { implies } g(u)=\bigcirc\left(\left\|T u_{0}\right\|\right) \tag{8.1}
\end{equation*}
$$

for these solutions $u=u(T)$ of $T u=\theta$.
In order to get the continuity it is sufficient essentially that $\Delta T=T-T_{0}$ tends to zero at the single point $u_{0}$. But for the purpose of calculating a Fréchet-derivative of $u(T)$ we have to know what the behaviour of $T$ is in a neighborhood of $u_{0}$ as $\left\|T u_{0}\right\|=\left\|\Delta T u_{0}\right\| \rightarrow 0$. According to the definition of the derivative we are looking for a linear operator $L$ such that the expression

$$
u\left(T_{0}+\Delta T\right)-u\left(T_{0}\right)-L \Delta T
$$

tends to zero faster than of order one as $\Delta T \rightarrow 0$ in a certain sense. But if we state the formula

$$
\begin{align*}
u(T)-u\left(T_{0}\right) & =-T_{0\left(u_{0}\right)}^{\prime-1} \Delta T u+\bigcirc\left(\left\|u-u_{0}\right\|\right)  \tag{8.2}\\
& =+T_{0\left(u_{0}\right)}^{\prime-1} T_{0} u+\bigcirc\left(\left\|u-u_{0}\right\|\right)
\end{align*}
$$

which follows from

$$
T_{0} u-T_{0} u_{0}-T_{0\left(u_{0}\right)}^{\prime}\left(u-u_{0}\right)=\bigcirc\left(\left\|u-u_{0}\right\|\right)
$$

observing that $T_{0} u_{0}=\theta$ and $T u=\theta$, we get the difficulty that normally $u(T)$ and $T_{0} u$ don't depend linearly on $T u_{0}$ or, equivalently, $\circ\left(\left\|u-u_{0}\right\|\right)$ is not $\circ(\|\Delta T u\|)$ in general.

Therefore, we make the following natural assumption:
A. We assume that all operators $T$ are differentiable at the point $u_{0}$ and that $T_{\left(u_{0}\right)}^{\prime}$ tends to an operator $\widetilde{T}_{\left(u_{0}\right)}^{\prime}$ for $\left\|T u_{0}\right\| \rightarrow 0$ such that
$\left(\widetilde{T}_{\left(u_{0}\right)}^{\prime}-T_{\left(u_{0}\right)}^{\prime}\right)\left(u-u_{0}\right)=O\left(\left\|T u_{0}\right\|\right)$ for $\quad u=u(T), u_{0}=u\left(T_{0}\right)$
and $\tilde{T}_{\left(u_{0}\right)}^{\prime}$ has a bounded inverse.
The normal case is $\widetilde{T}_{\left(u_{0}\right)}^{\prime}=T_{0\left(u_{0}\right)}^{\prime}$, as for example in the usual implicit function theorems. A is more general.

Under this assumption we have the
Theorem 8.1. Let $T_{0}$ satisfy the assumptions of Theorem 7.1 and let $\Omega$ be the ( $\left.u_{0}, r, a, b\right)$-neighborhood of $T_{0}$ in which the equation (7.3) $T u=\theta$ is uniquely and continuously solvable. Furthermore, we assume that all $T \varepsilon \Omega$ satisfy the differentiability condition $A$.

Then there exists a unique $F$-differential of the solution $u(T)$ of (7.3) at the "point" $T=T_{0}$ which has the form

$$
\begin{equation*}
u^{\prime}\left(T_{0}\right) \Delta T_{0}=-\widetilde{T}_{\left(u_{0}\right)}^{\prime-1} \Delta T_{0} u_{0} \tag{8.4}
\end{equation*}
$$

where

$$
u_{0}=u\left(T_{0}\right) \quad \text { and } \quad \Delta T_{0} u_{0}=\left(T-T_{0}\right) u_{0}=T u_{0}
$$

Proof. By definition of the $F$-differential of $T$,

$$
\begin{aligned}
\Delta T_{0} u_{0} & =T u_{0}=T u-T_{\left(u_{0}\right)}^{\prime}\left(u-u_{0}\right)+\bigcirc\left(\left\|u-u_{0}\right\|\right) \\
& =-T_{\left(u_{0}\right)}^{\prime}\left(u-u_{0}\right)+\circ\left(\left\|u-u_{0}\right\|\right)
\end{aligned}
$$

because $T u=\theta$. Hence it follows by (8.3) and (8.1) that

$$
\Delta T_{0} u_{0}=-\tilde{T}_{\left(u_{0}\right)}^{\prime}\left(u-u_{0}\right)+\bigcirc\left(\left\|T u_{0}\right\|\right)
$$

or because of the existence of a bounded inverse that

$$
\begin{equation*}
u(T)-u\left(T_{0}\right)+\widetilde{T}_{\left(u_{0}\right)}^{\prime-1} \Delta T_{0} u_{0}=O\left(\left\|\Delta T_{0} u_{0}\right\|\right), \tag{8.5}
\end{equation*}
$$

which implies (8.4) by definition of the $F$-differential.
There cannot be more than one such derivative. For let $L_{1}$ and $L_{2}$ be two linear operators satisfying (8.5). It results from (8.5) with $\lambda \Delta T_{0} u_{0}$ (for fixed $\Delta T_{0} u_{0}$ and real $\lambda$ ) instead of $\Delta T_{0} u_{0}$

$$
\left\|\left(L_{1}-L_{2}\right) \Delta T_{0} u_{0}\right\|=\varphi(\lambda) \quad \text { with } \quad \varphi(\lambda) \rightarrow 0 \quad \text { as } \quad \lambda \rightarrow 0,
$$

which implies $L_{1}=L_{2}$. This completes the proof.
In the special case $T u=T^{*} u-w, T_{0} u=T^{*} u-w_{0}$ and $T^{*} u_{0}=w_{0}$ the condition $A$ is satisfied with $\widetilde{T}_{\left(u_{0}\right)}^{\prime}=T_{0\left(u_{0}\right)}^{\prime}$ because of $T_{\left(u_{0}\right)}^{\prime}=T_{0\left(u_{0}\right)}^{\prime}$ and assumption $b$ ) of Theorem 7.1. By writing again $T$ for $T^{*}$ we get the following inverse function theorem as a corollary:

Theorem 8.2. a) Let $T$ be defined on the sphere $S_{0}=S\left(u_{0}, r_{0}\right) \subset B_{1}$ and let

$$
T u_{0}=w_{0} .
$$

Furthermore, let the assumptions b) and c) of Theorem 7.1 be satisfied.

Then $T$ has a local inverse $T^{-1}$ defined in a neighborhood of $w_{0}$ and $T^{-1}$ has a bounded derivative at the point $w_{0}$ :

$$
\begin{gather*}
u(w)=T^{-1} w, \quad u\left(w_{0}\right)=T^{-1} w_{0}, \\
u^{\prime}\left(w_{0}\right) \Delta w=\left(T^{-1}\right)_{\left(w_{0}\right)}^{\prime} \Delta w=\left(T_{\left(u_{0}\right)}^{\prime}\right)^{-1} \Delta w \tag{8.6}
\end{gather*}
$$

with $\Delta \mathscr{w}=W-W_{0}$.
In these theorems it is not required that $T$ and $T_{\left(u_{0}\right)}^{\prime}$ are continuous although a continuous derivative of the inverse function is asserted. Thus certain differential operators like $F\left(x, \lambda, u, u^{\prime}, \ldots, u^{(r)}\right)$ plus certain conditions can be treated.

In the special case of an equation

$$
T u \equiv T(x) u \equiv T(x, u)=\theta, \quad T_{0} u_{0}=T\left(x_{0}, u_{0}\right)=\theta
$$

with $x, u, T u$ in Banach spaces we get the usual implicit function theorem with

$$
u(T)=u(T(x))=\varphi(x), \quad u\left(T_{0}\right)=\varphi\left(x_{0}\right)
$$

if we assume that there are $F$-differentials $T_{(u)}^{\prime}(x) k$, continuous in a neighborhood of $\left(x_{0}, u_{0}\right)$ and with bounded operator $T_{\left(u_{0}\right)}^{\prime-1}\left(x_{0}\right)$, and $T_{\left(x_{0}\right)}^{\prime}\left(u_{0}\right) h$. Then

$$
\tilde{T}_{\left(u_{0}\right)}^{\prime}=T_{\left(u_{0}\right)}^{\prime}(x) \quad \text { and } \quad \varphi^{\prime}\left(x_{0}\right) h=u^{\prime}(T) T_{\left(x_{0}\right)}^{\prime}\left(u_{0}\right) h,
$$

and there results the well known formula

$$
\begin{equation*}
\varphi^{\prime}\left(x_{0}\right)=-T_{\left(u_{0}\right)}^{\prime-1} \cdot T_{\left(x_{0}\right)}^{\prime}\left(u_{0}\right) . \tag{8.7}
\end{equation*}
$$

In order to calculate the second $F$-differential of the solution $u(T)$ of the equation $T u=\theta$ at $T=T_{0}$ we assume that $T$ has a first and a second $F$-derivative (with respect to $u$ ) which are continuous ${ }^{1}$ ) in a neighborhood of $u_{0}$. Then also $u^{\prime}(T)$ is continuous " around $T_{0}$ ", i.e. for fixed $h=\Delta^{*} T$

$$
\left\|u^{\prime}\left(T_{0}+\Delta T_{0}\right) h-u^{\prime}\left(T_{0}\right) h\right\| \rightarrow 0 \quad \text { as } \quad\left\|\Delta T_{0} u_{0}\right\| \rightarrow 0
$$

Furthermore, according to the case when the operator $T$ depends on the elements of a Banach space $B_{3}$, i.e. $T u=T(x) u$, $x \in B_{3}$, where $\Delta T u=T(x+h) u-T(x) u$, we define $\Delta$ to be a linear operation:

$$
\Delta\left(T_{1}+T_{2}\right) u=\Delta T_{1} u+\Delta T_{2} u, \quad \Delta(\lambda T u)=\lambda \Delta T u .
$$

Then

$$
\Delta_{1}\left(T+\Delta_{2} T\right) u=\Delta_{1} T u+\Delta_{1} \Delta_{2} T u
$$

and $\Delta_{1} \Delta_{2} T u$ is linear in $\Delta_{1}$ and $\Delta_{2}$.
With these natural assumptions the calculation of the second order $F$-derivative as a bilinear operator is a straight-forward derivation. We use the formula

$$
\begin{equation*}
\Delta_{1} T u(T)+T_{(u)}^{\prime} u^{\prime}(T) \Delta_{1} T=\theta \tag{8.8}
\end{equation*}
$$

at the "points" $T=T_{0}$ and $T=T_{0}+\Delta_{2} T_{0}$ and take the

[^0]difference of the two expressions retaining only those terms which are linear in $\Delta_{2}$. For the sake of brevity we use the following abbreviations:
\[

$$
\begin{aligned}
& u_{0}=u\left(T_{0}\right), \quad T=T_{0}+\Delta_{2} T_{0}, \quad u=u(T)=u\left(T_{0}+\Delta_{2} T_{0}\right) \\
& O_{2}=\circ\left(\left\|\Delta_{2} T_{0} u_{0}\right\|\right)
\end{aligned}
$$
\]

Then we have

$$
\begin{aligned}
u(T) & =u_{0}+u^{\prime}\left(T_{0}\right) \Delta_{2} T_{0}+O_{2}, \\
k & =u^{\prime}(T) \Delta_{1} T=u^{\prime}\left(T_{0}+\Delta_{2} T_{0}\right)\left(\Delta_{1} T_{0}+\Delta_{1} \Delta_{2} T_{0}\right) \\
& =u^{\prime}\left(T_{0}+\Delta_{2} T_{0}\right) \Delta_{1} T_{0}+u^{\prime}\left(T_{0}\right) \Delta_{1} \Delta_{2} T_{0}+O_{2}, \\
\Delta_{1} T u(T) & -\Delta_{1} T_{0} u_{0}=\Delta_{1} T_{0} u+\Delta_{1} \Delta_{2} T_{0} u-\Delta_{1} T_{0} u_{0} \\
& =\Delta_{1} T_{0\left(u_{0}\right)}^{\prime} u^{\prime}\left(T_{0}\right) \Delta_{2} T_{0}+\Delta_{1} \Delta_{2} T_{0} u_{0}+O_{2}, \quad \text { and } \\
T_{0(u)}^{\prime} k & =T_{0\left(u_{0}\right)}^{\prime} k+T_{0\left(u_{0}\right)}^{\prime \prime}\left[u^{\prime}\left(T_{0}\right) \Delta_{2} T_{0}\right]\left[u^{\prime}\left(T_{0}\right) \Delta_{1} T_{0}\right]+O_{2} .
\end{aligned}
$$

Hence

$$
\begin{aligned}
T_{(u)}^{\prime} u^{\prime}(T) \Delta_{1} T & =\left(T_{0}+\Delta_{2} T_{0}\right)_{\left(u\left(T_{0}+\Delta_{2} T_{0}\right)\right)} u^{\prime}\left(T_{0}+\Delta_{2} T_{0}\right) \Delta_{1}\left(T_{0}+\right. \\
\left.\Delta_{2} T_{0}\right) & =\left[T_{0(u)}^{\prime}+\left(\Delta_{2} T_{0}\right)_{(u)}^{\prime}\right] k=T_{0(u)}^{\prime} k+\Delta_{2} T_{0\left(u_{0}\right)}^{\prime} k \\
& =T_{0(u)}^{\prime} k+\Delta_{2} T_{0\left(u_{0}\right)}^{\prime} u^{\prime}\left(T_{0}\right) \Delta_{1} T_{0}+O_{2} .
\end{aligned}
$$

Therefore, by (8.8)

$$
\begin{aligned}
\theta & =\Delta_{1} T u+T_{(u)}^{\prime} u^{\prime}(T) \Delta_{1} T-\Delta_{1} T_{0} u_{0}-T_{0\left(u_{0}\right)}^{\prime} u^{\prime}\left(T_{0}\right) \Delta_{1} T_{0} \\
& =\Delta_{1} T_{0\left(u_{0}\right)}^{\prime} u^{\prime}\left(T_{0}\right) \Delta_{2} T_{0}+\Delta_{1} \Delta_{2} T_{0} u_{0}+T_{0\left(u_{0}\right)}^{\prime}\left[u^{\prime}(T) \Delta_{1} T_{0}\right. \\
& \left.-u^{\prime}\left(T_{0}\right) \Delta_{1} T_{0}\right]+T_{0\left(u_{0}\right)}^{\prime} u^{\prime}\left(T_{0}\right) \Delta_{1} \Delta_{2} T_{0}+\Delta_{2} T_{0\left(u_{0}\right)}^{\prime} u^{\prime}\left(T_{0}\right) \Delta_{1} T_{0} \\
& +T_{0\left(u_{0}\right)}^{\prime \prime}\left[u^{\prime}\left(T_{0}\right) \Delta_{2} T_{0}\right]\left[u^{\prime}\left(T_{0}\right) \Delta_{1} T_{0}\right]+O_{2} .
\end{aligned}
$$

If we assume as above that $T_{0\left(u_{0}\right)}^{\prime}$ has a bounded inverse we finally get

$$
\begin{aligned}
u^{\prime}\left(T_{0}+\right. & \left.\Delta_{2} T_{0}\right) \Delta_{1} T_{0}-u^{\prime}\left(T_{0}\right) \Delta_{1} T_{0} \\
& +T_{0\left(u_{0}\right)}^{\prime-1}\left\{\Delta_{1} T_{0\left(u_{0}\right)}^{\prime} u^{\prime}\left(T_{0}\right) \Delta_{2} T_{0}+\Delta_{2} T_{0\left(u_{0}\right)}^{\prime} u^{\prime}\left(T_{0}\right) \Delta_{1} T_{0}\right. \\
+ & \Delta_{1} \Delta_{2} T_{0} u_{0}+T_{0\left(u_{0}\right)}^{\prime} u^{\prime}\left(T_{0}\right) \Delta_{1} \Delta_{2} T_{0}+T_{0\left(u_{0}\right)}^{\prime \prime}\left[u^{\prime}\left(T_{0}\right) \Delta_{2} T_{0}\right] \\
& \left.\quad\left[u^{\prime}\left(T_{0}\right) \Delta_{1} T_{0}\right]\right\}+O\left(\left\|\Delta_{2} T_{0} u_{0}\right\|\right) .
\end{aligned}
$$

Therefore, the second order differential of the solution $u(T)$ of $T u=\theta$ is given by

$$
\begin{gather*}
u^{\prime \prime}\left(T_{0}\right) \Delta_{2} T_{0} \Delta_{1} T_{0}=-T_{0\left(u_{0}\right)}^{\prime-1}\left\{\Delta_{1} T_{0\left(u_{0}\right)}^{\prime} u^{\prime}\left(T_{0}\right) \Delta_{2} T_{0}\right. \\
+\Delta_{2} T_{0\left(u_{0}\right)}^{\prime} u^{\prime}\left(T_{0}\right) \Delta_{1} T_{0}+\Delta_{1} \Delta_{2} T_{0} u_{0}+T_{0\left(u_{0}\right)}^{\prime \prime}  \tag{8.9}\\
\left.\left[u^{\prime}\left(T_{0}\right) \Delta_{2} T_{0}\right]\left[u^{\prime}\left(T_{0}\right) \Delta_{1} T_{0}\right]\right\}-u^{\prime}\left(T_{0}\right) \Delta_{1} \Delta_{2} T_{0} .
\end{gather*}
$$

Here

$$
u^{\prime}\left(T_{0}\right) \Delta T_{0}=-T_{\left(u_{0}\right)}^{\prime-1} \Delta T_{0} u_{0} .
$$

It is obvious that instead of the boundedness of $T_{0\left(u_{0}\right)}^{\prime}$ the weaker condition $A$ with $\widetilde{T}_{\left(u_{0}\right)}^{\prime}=T_{0\left(u_{0}\right)}^{\prime}$ and $T u_{0}=\Delta_{2} T_{0} u_{0}$ is sufficient for the existence of a differential of second order given by the formula (8.9). The considerations also show the existence of an $F$-derivative of $n$-th order and how to calculate it if $T$ has $F$-derivatives up to the order $n$ which are continuous in a neighborhood of $u_{0}$ with the possible exception that $T_{\left(u_{0}\right)}^{\prime}$ satisfies condition $A$ instead of the continuity condition. The uniqueness of the second order derivative can be shown as in the case of the first order derivative.

Example. For the special case
$T u \equiv T(x) u \equiv T(x, u)=\theta, \quad T_{0} u \equiv T\left(x_{0}, u\right), \quad T_{0} u_{0}=\theta$, we now write $T_{x}(x, u), T_{u}(x, u), T_{x x}(x, u)$ etc. for $T_{(x)}^{\prime}$, $T_{(u)}^{\prime}, T_{(x)}^{\prime \prime}$ respectively in accordance with the usual notation of partial derivatives of a function of more than one variable. ${ }^{1}$ )

Assuming $x, u, T(x, u)$ to be elements of Banach spaces we have with

$$
u(T)=u(T(x))=\varphi(x)
$$

the expressions

$$
\begin{equation*}
\varphi^{\prime}(x) h=u^{\prime}(T) T_{x} h, \tag{8.10}
\end{equation*}
$$

and
$\varphi^{\prime \prime}(x) h_{2} h_{1}=u^{\prime \prime}(T(x))\left(T_{x} h_{2}\right)\left(T_{x} h_{1}\right)+u^{\prime}(T(x)) T_{x x} h_{2} h_{1}$,
where the differentials are supposed to be Fréchet-differentials. Furthermore, we have

$$
\Delta_{i} T_{0}=T\left(x_{0}+h_{i}\right)-T\left(x_{0}\right)=T_{x}\left(x_{0}\right) h_{i}+\circ\left(h_{i}\right), \quad i=1,2
$$

[^1]\[

$$
\begin{aligned}
\Delta_{2} \Delta_{1} T_{0} & =\Delta_{1} \Delta_{2} T_{0} \\
& =T\left(x_{0}+h_{2}+h_{1}\right)-T\left(x_{0}+h_{1}\right)-T\left(x_{0}+h_{2}\right)-T\left(x_{0}\right) \\
& =T_{x}\left(x_{0}+h_{1}\right) h_{2}-T_{x}\left(x_{0}\right) h_{2}+\circ\left(h_{2}\right) \\
& =T_{x x} h_{1} h_{2}+\circ\left(h_{1}\right)+O\left(h_{2}\right),
\end{aligned}
$$
\]

and
$\Delta_{i} T_{0\left(u_{0}\right)}^{\prime}=T_{u}\left(x_{0}+h_{i}, u_{0}\right)-T_{u}\left(x_{0}, u_{0}\right)=T_{x u} h_{i}+\circ\left(h_{i}\right), \quad i=1,2$.
Hence by (8.9) and (8.10), neglecting the terms $\bigcirc\left(h_{i}\right)$, it results

$$
\begin{gathered}
\varphi^{\prime \prime}\left(x_{0}\right) h_{2} h_{1}=-\left(T_{u}\right)^{-1}\left\{T_{x u}\left(h_{1}\left[\varphi^{\prime}\left(x_{0}\right) h_{2}\right]+h_{2}\left[\varphi^{\prime}\left(x_{0}\right) h_{1}\right]\right)\right. \\
\left.+T_{x x} h_{1} h_{2}+T_{u u}\left[\varphi^{\prime}\left(x_{0}\right) h_{1}\right]\left[\varphi^{\prime}\left(x_{0}\right) h_{2}\right]\right\}
\end{gathered}
$$

where the derivatives of $T$ are taken at the point $\left(x_{0}, u_{0}\right)$ [e.g. $\left.T_{u}=T_{u}\left(x_{0}, u_{0}\right)\right]$ and, for example, $T_{x u} h k$ means that the bilinear operator $T_{x u}=T_{x u}\left(x_{0}, u_{0}\right)$ applies to the elements $h$ and $k$. Here $\varphi^{\prime}\left(x_{0}\right) h$ can be expressed by $-T_{u}^{-1} T_{x} h$ according to (8.7).
9. A global existence theorem using the differentiability of the operator

In this chapter a method for the proof of the existence of a solution of a non-linear equation

$$
\begin{equation*}
T u=\theta, \tag{9.1}
\end{equation*}
$$

is introduced which may be useful in cases where $T$ has a derivative but cannot be written in the form $I-V$ with completely continuous operator $V$ or in which the complete continuity of $V$ is difficult to show.

Theorem 9.1. Assume $T$ is a closed ${ }^{1}$ ) operator defined on an (open) domain $D \subset B_{1}$ and there has a derivative $T_{(u)}^{\prime}$ such that $T_{(u)}^{\prime}-T_{(v)}^{\prime}(u, v \in D)$ is bounded and continuous $\left.{ }^{2}\right)$ with respect to $u$. The range of $T$ lies in $B_{2}$.

[^2]
[^0]:    1) Less would suffice here, see below.
[^1]:    1) The previous notation, however, seems to be more usual in functional analysis
[^2]:    ${ }^{1)}$ See, for example, E. Hille and R. S. Phillips [4], p. 40, or N.I. Achieser and I. M. Glasmann [14], p. 82.
    ${ }^{2}$ ) We don't require that $T^{\prime}(\mathrm{u})^{\mathrm{k}}$ is continuous with respect to k .
