FLATNESS AND PRIVILEGE

by A. DOUADY

I. FLAT MORPHISMS

§ 1. *Analytic subspaces of an analytic space*

Let Y_1 and Y_2 be closed analytic subspaces of an analytic space X, and let them be defined by the $\mathcal{O}_X$ ideals J_1, J_2.

Definition 1 : We say that Y_1 is *analytically included* in Y_2, and we write $Y_1 \subset Y_2$, when $J_1 \supset J_2$.

Remark : The analytic inclusion implies the set theoretic inclusion, but the converse is not true.

Example: $X = (\mathbf{C}, \mathcal{O}_{\mathbf{C}})$; $J_1 = (x)$, $J_2 = (x^2)$. The space Y_1 is a simple point, Y_2 is a double point, $Y_1 \not\subset Y_2$, while they have the same underlying set.

Definition 2 : The subspace $Y_1 \cup Y_2$ is the smallest subspace of X containing Y_1 and Y_2, and it is defined by $J_1 \cap J_2$. The subspace $Y_1 \cap Y_2$ is the biggest subspace of X contained in both Y_1 and Y_2, and it is defined by $J_1 + J_2$.

Remark : The underlying set of $Y_1 \cup Y_2$ (Resp. $Y_1 \cap Y_2$) is the union (Resp. intersection) of the underlying sets of Y_1 and Y_2. However $\cup$ and $\cap$ of analytic spaces do not satisfy the distributivity laws which hold in set-theory: $(Y_1 \cup Y_2) \cap Y_3$ contains $Y_1 \cap Y_3$ and $Y_2 \cap Y_3$, and therefore their union; similarly $(Y_1 \cap Y_2) \cup Y_3 \subset (Y_1 \cup Y_3) \cap (Y_2 \cup Y_3)$. In general the converse inclusions do not hold.

Example: Let $X = \mathbf{C}^2$ and Y_1, Y_2, Z be given by ideals $(x-y)$, $(x+y)$ and (x) respectively.

$(Y_1 \cup Y_2) \cap Z$ is $\{0\}$ provided with $\mathbf{C}\{y\}/(y^2)$, while $(Y_1 \cap Z) \cup (Y_2 \cap Z)$ is the reduced space $\{0\}$. On the other hand: $Y_1 \cap Y_2 \subset Z$, $(Y_1 \cap Y_2) \cup Z = Z$, while $(Y_1 \cup Z) \cap (Y_2 \cup Z)$ is the space defined by the ideal (x^2, xy). Its local ring at the origin is $\mathbf{C}\{x, y\}/(x^2, xy)$ in which x is nilpotent.

Definition 3 : Let X', X be analytic spaces, Y a closed analytic subspace of X defined by J, and $f = (f_0, f^1) : X' \to X$ a morphism.

The inverse image of Y by f, $f^{-1}(Y)$, is the analytic subspace Y' of X' defined by the ideal $J' = f^1(J)\, \mathcal{O}_{X'}$.

The inverse image of a simple point x in X is called the *f*-fiber over x, and is denoted by $f^{-1}(x)$ or $X'(x)$.

Proposition 1 : If $f = (f_0, f^1) : X' \to X$ is a morphism of analytic spaces, and Y is a subspace of X, then $f^{-1}(Y) \simeq Y \underset{X}{\times} X'$.

Proof : Let T be any analytic space, and $g : T \to X'$ a morphism. Then g can be considered as a morphism from T to $f^{-1}(Y)$ if and only if $f \circ g$ can be considered as a morphism from T to Y. Thus $f^{-1}(Y)$ and $X' \underset{X}{\times} X$ are solutions of the same universal problem.

§ 2. *Analytic pull-back*

In the following we want to generalize the notion of inverse image of a subspace.

We shall first recall the basic properties of the tensor product $E \underset{A}{\otimes} F$, where A is a commutative ring and E, F are two A-modules.

(1°) $E \otimes A^n = E^n$ $(n \in N)$

(2°) If the sequence of A-modules $F' \to F \to F'' \to 0$ is exact, then also the sequence $E \otimes F' \to E \otimes F \to E \otimes F'' \to 0$ is exact. (Right exactness of the tensor product)

(3°) If $(F_i)_{i \in I}$; $f_{ij} : F_j \to F_i$ is an inductive system, then

$$E \otimes \varinjlim F_i = \varinjlim (E \otimes F_i).$$

On the other hand these properties characterize completely the functor $\otimes$.

Definition 1 : Let $f = (f_0\ f^1) : X' \to X$ be a morphism of analytic spaces, and $\mathcal{E}$ an $\mathcal{O}_X$-module. Then $f_0^* \mathcal{E}$ is an $f_0^* \mathcal{O}_X$-module and $\mathcal{O}_{X'}$ is also an $f_0^* \mathcal{O}_X$-module (by $f^1 : f_0^* \mathcal{O}_X \to \mathcal{O}_{X'}$).

The analytic pull-back $f^* \mathcal{E}$ of $\mathcal{E}$ by f is defined by scalar extension :

$$f^* \mathcal{E} = f_0^* \mathcal{E} \underset{f_0^* \mathcal{O}_X}{\otimes} \mathcal{O}_{X'}$$

Remark : The inverse image is a particular case of the analytic pull-back.

In fact, if Y is a closed analytic subspace of X and $f : X' \to X$ is a morphism :

$$f^* \mathcal{O}_Y = f_0^*(\mathcal{O}_X/J_Y) \underset{f_0^* \mathcal{O}_X}{\otimes} \mathcal{O}_{X'} \simeq f_0^* \mathcal{O}_X/f_0^* J_Y \underset{f_0^* \mathcal{O}_X}{\otimes} \mathcal{O}_{X'}$$

$$\simeq \mathcal{O}_{X'}/f^1(J_Y) . \mathcal{O}_{X'} \simeq \mathcal{O}_{f^{-1}(Y)}$$

(The third isomorphism follows from the fact, that $A/I \underset{A}{\otimes} E \simeq E/IE$).

Elementary properties of the analytic pull-back :

(a) $(f^* \mathcal{E})_{x'} = (f_0^* \mathcal{E})_{x'} \underset{(f_0^* \mathcal{O}_X)_{x'}}{\otimes} \mathcal{O}_{X',x'} \simeq \mathcal{E}_x \underset{\mathcal{O}_{X,x}}{\otimes} \mathcal{O}_{X',x'}$ where $x = f_0(x')$ (since $\otimes$ commutes with inductive limits).

(b) $f^* (\mathcal{E} \underset{\mathcal{O}X}{\otimes} \mathcal{F}) = f^* \mathcal{E} \underset{\mathcal{O}X'}{\otimes} f^* \mathcal{F}$, where $\mathcal{E}$ and $\mathcal{F}$ are $\mathcal{O}_X$-modules.

(c) If $\mathcal{E}$ is a coherent $\mathcal{O}_X$-module, then $f^* \mathcal{E}$ is a coherent $\mathcal{O}_{X'}$-module.

In fact, $\mathcal{E}$ has a locally finite presentation :
$\mathcal{O}_X^q \to \mathcal{O}_X^p \to \mathcal{E} \to 0$, and f^* is compatible with cokernels, $f^* (\mathcal{O}_X^r) = \mathcal{O}_X^r$.

Special case : The pull-back of vector bundle. Let (E, π) be an analytic vector bundle over the analytic space X, and $f: X' \to X$ a morphism of analytic spaces. The fiber product carries a unique structure of vector bundle over X', such that $\bar{f}$ is a bundle morphism. We call this bundle E'.

$$\begin{array}{ccc} E \underset{X}{\times} X' & \xrightarrow{\bar{f}} & E \\ \downarrow{\pi'} & & \downarrow{\pi} \\ X' & \xrightarrow{f} & X \end{array}$$

Proposition 1 : Let $\mathcal{E}$ (Resp. $\mathcal{E}'$) be the sheaf of analytic sections of E (Resp. E'). Then $\mathcal{E}' = f^* \mathcal{E}$.

Proof (Sketch) : We have a $f_0^* \mathcal{O}_X$ linear morphism $f_0^* \mathcal{E} \to \mathcal{E}'$, which extends to a morphism $f^* \mathcal{E} \to \mathcal{E}'$. We can prove that this is an isomorphism. Since the question is local with respect to X', we can suppose that E is a trivial bundle over X with fiber $\mathbf{C}^r$, then $\mathcal{E} = \mathcal{O}_X^r$. Also $\mathcal{O}_{X'}^r = f^* \mathcal{O}_X^r$. Therefore $f^* \mathcal{E} = \mathcal{E}'$.

§ 3. *Introduction to flatness by examples*

Let S be an analytic space. By analytic space over s we mean an analytic space X provided with a morphism $\pi : X \to S$. Let S be a simple point in S, and consider $X(s) = f^{-1}(s)$.

The main purpose of these lectures is to give a precise meaning to the expression:

"$X(s)$ depends nicely on s", and to give a criterion for the "nice" behaviour.
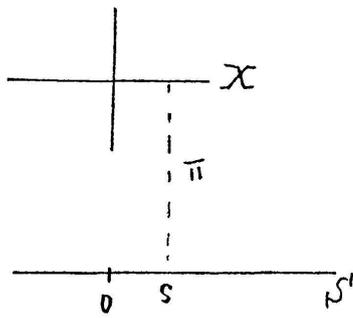

We begin with some examples.

Example 1: X is the closed subspace on $\mathbf{C}^2$ defined by $(y^2 - x)$, $S = \mathbf{C}$ and $\pi = $ 1st projection.
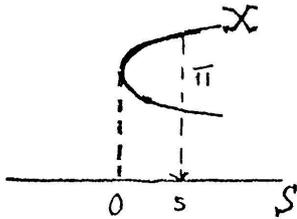

$$X(s) = \begin{cases} 2 \text{ simple points if } s \neq 0 \\ \text{double point if } \quad s = 0. \end{cases}$$

Here the behaviour of $X(s)$ is nice.

Example 2: X is the closed subspace of $\mathbf{C}^2$ defined by (xy), $S = \mathbf{C}$ and $\pi = $ 1st projection.

$X(s)$ is given by $(x-s, xy)$, and

$$(x-s, xy) = \begin{cases} (x-s, y) & \text{if } \quad s \neq 0 \\ (x) & \text{if } \quad s = 0. \end{cases}$$

The first case is a simple point, the second one the, y-axis.

A similar example is the map of a point into $\mathbf{C}$.

In both of these examples the dimension of the fiber makes a jump at one point. We notice, however, that the exceptional point corresponds to an irreductible component of X, and after removing this component π behaves nicely.

This kind of removing is not possible in general, as the following example shows:

Example 3: X is given in $\mathbf{C}^3$ by $(xz - y)$, and π is the projection on the (x, y)-plane.

If $s = (x_0, y_0)$, then the fiber $X(s)$ is defined by

$$(x - x_0, y - y_0, xz - y) = \begin{cases} \left(x - x_0, y - y_0, z - \dfrac{y_0}{x_0}\right) \text{ if } x_0 \neq 0 \\ (x, y) \qquad\qquad\qquad \text{if } \quad x_0 = y_0 = 0 \\ (1) \quad \text{if } \quad x_0 = 0 \, y_0 \neq 0. \end{cases}$$

The set of " nice " fibers is dense in X, so we cannot remove the z-axis and still get a closed subspace of $\mathbf{C}_3$.

§ 4.   Algebraic study of flatness

In the following all rings are commutative, with 1, and all modules are unitary.

Definition 1 : An A-module E is *flat,* if for every exact sequence of A-modules

$$0 \rightarrow F' \rightarrow F \rightarrow F'' \rightarrow 0 \,,$$

the sequence $0 \rightarrow E \otimes F' \rightarrow E \otimes F \rightarrow E \otimes F'' \rightarrow 0$ is also exact. We can also say, because $\otimes$ is right exact, that E is flat, if for every injective homomorphism $F' \rightarrow F$, $E \otimes F' \rightarrow E \otimes F$ is also injective.

Examples of modules which are not flat :

(1) if $A = \mathbf{Z}$, $E = \mathbf{Z}_2 = \mathbf{Z}/2\,\mathbf{Z}$, $F = F' = \mathbf{Z}$; then the sequence $0 \rightarrow \mathbf{Z} \overset{2I}{\rightarrow} \mathbf{Z}$ $(2I : x' \rightarrow 2x)$ is exact. But now $\mathbf{Z}_2 \otimes \mathbf{Z} = \mathbf{Z}_2$, and the homomorphism $\mathbf{Z}_2 \overset{2I}{\rightarrow} \mathbf{Z}_2$ is the zero homomorphism, which is not injective. So $\mathbf{Z}_2$ is not a flat $\mathbf{Z}$ module.

(2) If $A = \mathbf{C}\{x\}, E = \mathbf{C} = \mathbf{C}\{x\}/(x), F = F' = \mathbf{C}\{x\}$, then the sequence $0 \rightarrow F \overset{xI}{\rightarrow} F'$ $(xI : p(x) \rightarrow xp(x))$ is exact. But the homomorphism $E \overset{xI}{\rightarrow} E$ is not injective.

Proposition 1 : If A is an integral domain and E a flat A-module, then E is torsion-free.

Proof : Let $a \in A$, $a \neq 0$. Because A is an integral domain, the sequence $0 \rightarrow A A \overset{aI}{\rightarrow}$ $(aI : x \rightarrow ax)$ is exact. Since E is flat, the sequence $0 \rightarrow E \overset{aI}{\rightarrow} E$ is also exact. In other words E has no torsion elements.

Proposition 2 : If A is a principal-ideal domain, then E is flat if and only if E is torsionfree.

Proof : See corollary of prop. 6.

Examples of flat modules :

(1) The inductive limit of flat modules is flat, because the inductive limit preserves exactness, and it commutes with the tensor product.

(2) Every free module is flat. In fact, if E is free and finite type, then $E = A^n$ and $E \otimes F = F^n$. If $F' \to F$ is injective, so is $F'^n \to F^n$ too.

If E is an arbitrary free module, then it is an inductive limit of free modules of finite type, and the flatness of E follows from (1).

(3) Let S be a multiplicative system in A. Then the ring of fractions $S^{-1}A$ is a flat A-module. In fact the ring $S^{-1}A$ can be identified with an inductive limit of free modules, so it is flat ((1) (2)). We assume for simplicity that S has only regular elements. We can define in the set S a partial order in the following way:

$$s' \geqq s \Leftrightarrow \exists\, t \in A, \quad ts = s' \quad \text{(such a } t \text{ is then unique)}.$$

Let $E_s = A$ for every $s \in S$, and if $s' \geqq s$ (i.e. $s' = ts$) then let $f\,_s^{s'}$ be the homomorphism $t \cdot I_A : E_s \to E_{s'}$. The family $(E_s)_{s \in S}$ with the homomorphisms $(f\,_s^{s'})$ is an inductive system.

Let $E = \lim_{\to} E_s$ be the inductive limit of this system, and φ_s the canonical homomorphism $E_s \to E$. We shall define an isomorphism $\psi : E \to S^{-1}A$.

We first define for every s a homomorphism $\psi_s : E_s = A \to S^{-1}A$; $x \to x/s$. Now if $s' \geqq s$, then

$$(\psi_{s'} \circ f\,_s^{s'})(x) = \psi_{s'}(tx) = \frac{tx}{s'} = \frac{tx}{ts} = \frac{x}{s} = \psi_s(x).$$

Therefore there exists a homomorphism $\psi : E \to S^{-1}A$, satisfying $\psi_s = \psi \circ \varphi_s$ for every $s \in S$.

Because every element of $S^{-1}A$ has the form a/s, ψ is surjective. On the other hand if $\psi(\phi_s(x)) = 0$, then $\psi_s(x) = x/s = 0$. Thus $x = 0$, and ψ is also injective.

The above proof can be extended to the general case, not assuming that the elements of S are regular. The extended proof involves the notion of inductive limit of an inductive system indexed by a category instead of an ordered set.

From (1) and (2) above, any module which is the inductive limit of free modules, is flat. Conversely:

Theorem 1 : (Daniel, Lazard)

Any flat module is a inductive limit of free modules.

For the proof: See *C.R. Acad. Sci. Paris,* 258 (1964), pp. 6313-6316.

Some elementary properties of flat modules :

(1) If E and F are flat A-modules, then $E \otimes F$ is also flat. In fact, if $G' \to G$ is injective, then $F \otimes G' \to F \otimes G$ is injective, and also $E \otimes (F \otimes G') \to \to E \otimes (F \otimes G)$ is injective. The result follows from the assosiativity of the tensor product.

(2) Let $\phi : A \to B$ be a ring homomorphism, and E a flat A-module. The module $B \underset{A}{\otimes} E$ is a flat B-module.

If F is a B-module, then $F \underset{B}{\otimes} (B \underset{A}{\otimes} E) = (F \underset{B}{\otimes} B) \underset{A}{\otimes} E = F \underset{A}{\otimes} E$ further if F' and F are B-modules, and $F' \to F$ an injective homomorphism of B-modules, we can consider this homomorphism as an injective homomorphism of A-modules. Because E is A-flat,

$$F' \otimes_A E \to F \otimes_A E \text{ is injective.}$$

(3) Let $\phi : A \to B$ be a ring homomorphism, such that B is a flat A-module. If F is a flat B-module, then F is a flat A-module. In fact :if $E' \to E$ is injective, then $E' \otimes B \to E \otimes B$ is injective, and also $(E \otimes B) \otimes F' \to (E \otimes B) \otimes F$ is injective. But $(E' \underset{A}{\otimes} B)_B \otimes F' = E' \otimes_A F$; $(E \underset{A}{\otimes} B) \underset{B}{\otimes} F = E \otimes_A F$.

If an A-module E is not flat, we want to measure how far it is from being flat. For this purpose we introduce the functor Tor.

Definition 2 : A free resolution of E is an exact sequence: $\ldots \to L_n \to L_{n-1} \to \to \ldots \to L_1 \to L_0 \to E \to 0$, where all L_i are free A-modules.

The complex of the resolution is the sequence

$$(L.) \ldots \to L_n \to L_{n-1} \to \ldots \to L_1 \to L_0 \to 0 .$$

Every module has a free resolution. Two resolutions are algebraically homotopy-equivalent. Forming the tensorproducts $L_i \otimes F$, we get

$$(L. \otimes F) \ldots \to L_n \otimes F \to L_{n-1} \otimes F \to \ldots \to L_1 \otimes F \to L_0 \otimes F \to 0 .$$

Definition 3 :

$$\mathrm{Tor}_n^A (E, \mathrm{F}) = H_n (L. \otimes F) = \frac{\mathrm{Ker}(L_n \otimes F \to L_{n-1} \otimes F)}{\mathrm{Im} (L_{n+1} \otimes F \to L_n \otimes F)}$$

if $n \geq 1$, and $\mathrm{Tor}_0^A (E, F) = \mathrm{Coker} (L_1 \otimes F \to L_0 \otimes F) = E \otimes F$.

Basic properties of Tor :

(1) $\mathrm{Tor}_n (E, F)$ is independent of the choice of the resolution (up to a canonical isomorphism).

(2) If we take a free resolution of F, we get $\mathrm{Tor}_n(F, E) = \mathrm{Tor}_n(E, F)$ (Symmetry of the Tor). We can also define $\mathrm{Tor}_n(E, F)$ by taking two free resolutions, one of E and one of F.

(3) If $0 \to E' \to E \to E'' \to 0$ is a short exact sequence, then we get a long exact sequence:

$$\mathrm{Tor}_n(E', F) \to \mathrm{Tor}_n(E, F) \to \mathrm{Tor}_n(E'', F) \qquad \to$$
$$\to \mathrm{Tor}_{n-1}(E', F) \to \mathrm{Tor}_{n-1}(E, F) \to \mathrm{Tor}_{n-1}(E'', F) \to$$
$$\to \text{— — — — — — — — — — — —} \to$$
$$\to \mathrm{Tor}_1(E', F) \to \mathrm{Tor}_1(E, F) \to \mathrm{Tor}_1(E'', F) \qquad \to$$
$$\to E' \otimes F \to E \otimes F \to E'' \otimes F \to 0 .$$

(4) Tor is compatible with inductive limit, i.e. if $E = \varinjlim (E_i)$, then
$$\mathrm{Tor}_n(\varinjlim E_i, F) = \varinjlim (\mathrm{Tor}_n(E_i, F)).$$

(5) We can define $\mathrm{Tor}_n(E, F)$ by taking a flat resolution of E.

Proposition 3: Let E be an A-module. Then the following conditions are equivalent:

(a) E is flat.

(b) For all A-modules F, and for all $n \geqq 1$, $\mathrm{Tor}_n(E, F) = 0$.

(c) For all A-modules F, $\mathrm{Tor}_1(E, F) = 0$.

Proof: $(a) \Rightarrow (b)$. If $\ldots \to L_n \to L_{n-1} \to \ldots \to L_1 \to L_0 \to F \to 0$ is a free resolution of F, then the sequence

$$\ldots \to E \otimes L_n \to E \otimes L_{n-1} \to \ldots \to E \otimes L_1 \to E \otimes L_0 \to E \otimes F \to 0$$

is exact, thus $\mathrm{Tor}_n(E, F) = 0$ for all $n \geqq 1$.

$(b) \Rightarrow (c)$ clear. $(c) \Rightarrow (a)$: If the sequence $0 \to F' \to F \to F'' \to 0$ is exact, so is also (by (3) above) $\mathrm{Tor}_1(E, F'') \to E \otimes F' \to E \otimes F \to E \otimes F'' \to 0$. Now $\mathrm{Tor}_1(E, F'') = 0$, thus E is flat.

Proposition 4: If I and J are two ideals in A, then $\mathrm{Tor}_1^A(A/I, A/J) = I \cap J / I . J$.

Proof: From the exact sequence $0 \to I \to A \to A/I \to 0$, we get the exact sequence:

$$\mathrm{Tor}_1(A, A/J) \to \mathrm{Tor}_1(A/I, A/J) \to I \otimes A/J \to A \otimes A/J \to A/I \otimes A/J \to 0 .$$

But now $\mathrm{Tor}_1(A, A/J) = 0$ (A beeing A-free), and $I \otimes A/J = I/I . J$; $A \otimes A/J = A/J$. Therefore the sequence $0 \to \mathrm{Tor}_1(A/I, A/J) \to I/I . J \to A/J$ is exact, and $\mathrm{Tor}_1(A/I, A/J) = \mathrm{Ker}(I/I . J \to A/J) = I \cap J / I . J$.

Example : Let U be an open set in $\mathbf{C}^n$, and $x \in U$. Further let $X, Y \subset U$ be two hypersurfaces, defined by $I = (f)$ and $J = (g)$. Supposing that f and g do not have common factors: $I_x \cap J_x = I_x J_x$, and

$$\mathrm{Tor}_1 \left(\mathcal{O}_{X,x}, \mathcal{O}_{Y,x} \right) = \mathrm{Tor}_1 \left(\mathcal{O}_{U,x}/I_x, \quad \mathcal{O}_{U,x}/J_x \right) = \frac{I_x \cap J_x}{I_x \cdot J_x} = 0.$$

Heuristic remark : The formula $\mathrm{Tor}_1 \left(\mathcal{O}_{X,x}, \mathcal{O}_{Y,x} \right) = 0$ expresses the fact that X and Y are " in general position ". If for example X and Y are two linears subspaces in $\mathbf{C}^n$ of dimensions p and q, we have $\mathrm{Tor}_1 \left(\mathcal{O}_{X,x}, \mathcal{O}_{Y,x} \right) = 0$ if $\dim (X \cap Y) = p + q - n$, and $\mathrm{Tor} \left(\mathcal{O}_{X,x}, \mathcal{O}_{Y,x} \right) \neq 0$ otherwise.

Next we shall prove an elementary flatness criterion.

Proposition 5 : Let E be an A-module. The following conditions are equivalent:

(*a*) E is flat.

(*b*) For all finitely generated ideals I of A, $\mathrm{Tor}_1 (E, A/I) = 0$.

(*c*) For all monogenous A-modules F, $\mathrm{Tor}_1 (E, F) = 0$.

Proof : (*a*) $\Rightarrow$ (*b*), by prop. 3.

(*b*) $\Rightarrow$ (*c*): Because Tor is compatible with inductive limit, we can suppose, that $\mathrm{Tor}_1 (E, A/I) = 0$ for an arbitrary ideal I of A. But every monogenous A-module F can be represented by A/I.

(*c*) $\Rightarrow$ (*a*). By prop. 3 it is sufficient to prove that $\mathrm{Tor}_1 (E, F) = 0$ for any A-module F.

First consider the case, where F is finitely generated. We use induction, supposing that $\mathrm{Tor}_1 (E, F) = 0$, when F has n generators. Let F have $(n+1)$ generators $x_1, \ldots, x_n, x_{n+1}$. If F' is the submodule generated by $\{x_1, \ldots, x_n\}$, then $F' \subset F$ and $F'' = F/F'$ is monogenous. The exact sequence $0 \to F' \to F \to F'' \to 0$ gives the exact sequence $\mathrm{Tor}_1 (E, F') \to \mathrm{Tor}_1 (E, F) \to \mathrm{Tor}_1 (E, F'')$. Now $\mathrm{Tor}_1 (E, F') = \mathrm{Tor}_1 (E, F'') = 0$, thus $\mathrm{Tor}_1 (E, F) = 0$. In the general case, F can be considered as an inductive limit of finitely generated modules, and because Tor is compatible with inductive limits, $\mathrm{Tor}_1 (E, F) = 0$.

Proposition 6 : Let A be an integral domain, and E an A-module. Then E is torsionfree if and only if $\mathrm{Tor}_1 (E, A/(a)) = 0$, for any element $a \in A$.

Proof : If E is A-module, $a \in A$, then the exact sequence $0 \to A \xrightarrow{aI} A \to A/(a) \to 0$ gives the exact sequence $0 \to \mathrm{Tor}_1 (E, A/(a)) \to E \xrightarrow{aI} E$. In other words $\mathrm{Tor}_1 (E, A/(a)) = \{x \in E \mid ax = 0\}$, from which the result follows.

Corollary : Let A be a principal ideal domain. E is flat if and only if E is torsionfree.

Proof : We have already proved that, if E is flat, then it is torsion free. The converse follows from prop. 6 and prop. 5.

The first flatness criterion for noetherian local rings is the following:

Theorem 2 : Let A be a noetherian local ring with maximal ideal m; $k = A/m$, and E a finitely generated A-module. The following conditions are equivalent:

(a) E is free.

(b) E is flat.

(c) $\operatorname{Tor}_1^A (E, k) = 0$.

Proof : We have already proved $(a) \Rightarrow (b) \Rightarrow (c)$.

$(c) \Rightarrow (a)$: We recall first Nakayma's lemma. If A is a local ring with maximal ideal m; $k=A/m$, and E is a finitely generated A-module, such that $k \underset{A}{\otimes} E = E/mE = 0$, then $E = 0$.

The module $\bar{E} = k \underset{A}{\otimes} E = E/mE$ is a finitely generated vector space over k. Let $\{\bar{x}_1. ..., \bar{x}_r\}$ be a base of $\bar{E}$ (over k), and $\{x_1, ..., x_r\}$ E representatives of $\bar{x}_i : s$. Consider the homomorphism $\phi : A^r \to E$, $\phi (a_1, ..., a_r) = \sum a_i x_i$. Denoting by R and Q the kernel and the cokernel of ϕ, we get an exact sequence:

(*) $$0 \to R \to A^r \to E \to Q \to 0$$

and R, Q are finitely generated A-modules. From (*) we get the exact sequence

$$A^r \underset{A}{\otimes} k \to E \underset{A}{\otimes} k \to Q \underset{A}{\otimes} k \to 0 .$$

But $\bar{E} = E \underset{A}{\otimes} k \simeq k^r = A^r \underset{A}{\otimes} k$, so $Q \underset{A}{\otimes} k = 0$, and by Nakayama's lemma $Q = 0$.

Therefore *ge* have an exact sequence

$$0 \to R \to A^r \to E \to 0 .$$

From this we get: $\operatorname{Tor}_1 (E, k) \to k \underset{A}{\otimes} R \to k^r \to \bar{E} \to 0$ (exact). Now: $\bar{E} \simeq k^r$, $\operatorname{Tor}_1 (E, k) = 0$ (by assumption). Therefore $k \underset{A}{\otimes} R = 0$, and once more by Nakayama's lemma $R = 0$, thus $E \simeq A^r$, i.e. E is free.

Proposition 7: Let $\phi : A \to B$ be a ring homomorphism, and let B be A-flat. If I is an ideal of A, we write $\bar{A} = A/I$, $\bar{B} = B/IB = \bar{A} \underset{A}{\otimes} B$. Let F be a B-module, then: $\operatorname{Tor}_i^A (\bar{A}, F) = \operatorname{Tor}_i^B (\bar{B}, F)$ $(i \geqq 0)$.

Proof: We choose first a B-free resolution of F

$$\to L_{n+1} \to L_n \to \ldots \to L_1 \to L_0 \to F \to 0 \ .$$

If $L.$ is the respective complex of resolution, then

$$\bar{B} \underset{B}{\otimes} L. = B/IB \underset{B}{\otimes} L. = \bar{A} \underset{A}{\otimes} (B \underset{B}{\otimes} L.) = \bar{A} \underset{A}{\otimes} L.$$

Because every L_i is B-free, and B is A-flat, every L_i is A-flat (Property 3 after Th. 1). Thus $L.$ is a flat A-resolution, and

$$\operatorname{Tor}_i^A (\bar{A}, F) = H_i (\bar{A} \underset{A}{\otimes} L.) = H_i (\bar{B} \underset{B}{\otimes} L.) = \operatorname{Tor}_i^B (\bar{B}, F) \ .$$

We shall next state the second flatness criterion for noetherian local rings.

Theorem 3: Let A and B be two noetherian local rings, with maximal ideals $\underline{m}, \underline{n}$; $k = A/\underline{m}$. If $\phi : A \to B$ is a local homomorphism (i.e. $\phi(\underline{m}) \subset \underline{n}$), and F finitely generated B module then

$$F \text{ is A-flat} \Leftrightarrow \operatorname{Tor}_1^A (k, F) = 0 \ .$$

The proof of this theorem is much more difficult than that of th. 20 see for example:

Bourbaki: *Algèbre commutative*, Chapter III § 5, th1, $(i) \Leftrightarrow (iii)$, p. 98.

The conditions in Bourbaki's theorem are here fullfilled:

1° A finitely generated module F over a noetherian local ring B is idealwise separated for $\underline{n}$. (*Ibid.*, § 5. 1. Ex. 1, p. 97.)

2° If $\phi : A \to B$ is a local homomorphism, F is also idealwise separated for $\underline{m}$. (*Ibid.*, § 5, prop. 2, p. 101.)

3° Also the flatness condition is fulfilled, because k is a field.

Remark: The main interest of the theorem lies in the fact, that it is true without any assumption of finitness on B.

Corollary: If the assumptions are the same as in the theorem 3, and if moreover B is A-flat, then

$$F \text{ is A-flat} \Leftrightarrow \operatorname{Tor}_1^B (\bar{B}, F) = 0 \ ,$$

where $\bar{B} = B/mB$.

Proof: $\mathrm{Tor}_1^A (k, F) = \mathrm{Tor}_1^B (\bar{B}, F)$, by prop. 7.

§ 5. *Geometric applications of the flatness criterions*

A) *Flatness for finite morphisms*

Proposition 1 : Let $\pi: X \to S$ be a finite morphism (i.e. proper with finite fibres) of analytic spaces. Then $\pi_* (\mathcal{O}_X)$ is a coherent analytic sheaf over S. The following conditions are equivalent:

(*a*) π is flat (i.e. for every $x \in X$, $\mathcal{O}_{X,x}$ is a flat $\mathcal{O}_{S,s}$-module, $s = \pi(x)$).

(*b*) For every s, $(\pi_* \mathcal{O}_X)_s$ is a flat $\mathcal{O}_{S,s}$-module.

(*c*) $\pi_* \mathcal{O}_X$ is a locally free sheaf.

Proof: Because π is finite $\pi_* (\mathcal{O}_X)_s = \bigoplus\limits_{x \varepsilon \pi^{-1}(s)} \mathcal{O}_{X,x}$, thus the only point to prove is (*b*) $\Rightarrow$ (*c*).

Now if $\mathcal{O}_{X,x}$ is a flat $\mathcal{O}_{S,s}$-module, then (by theorem 2) $\mathcal{O}_{X,x}$ is free, and a coherent sheaf whose fibers are free is a locally free sheaf.

Proposition 2 : Let S be a reduced analytic space and $\mathcal{E}$ a coherent $\mathcal{O}_s$-module. Let $E(s)$ be the finite dimensional vector space (over $\mathbf{C}$) $\mathcal{E}_s \otimes_{\mathcal{O}_{S,s}} \mathbf{C}_s$. $\mathcal{E}$ is a locally free $\mathcal{O}_{S,s}$-module if an only if $\dim_{\mathbf{C}} E(s)$ is locally constant.

Proof: If $\mathcal{E}$ is locally free, then $\dim_{\mathbf{C}} E(s)$ is locally constant. Suppose now that $\dim_{\mathbf{C}} E(s)$ is locally constant in an open set $U \subset S$, and that $\mathcal{O}_U^p \xrightarrow{d} \mathcal{O}_U^q \to \mathcal{E}_U \to 0$ is exact. d is determined by a $p \times q$ matrix of analytic functions on U, so it gives a morphism $\mathbf{C}_U^p \xrightarrow{d} \mathbf{C}_U^q$ of trivial vector bundles over U.

From the exact sequence $\mathcal{O}_s^p \xrightarrow{d_s} \mathcal{O}_s^q \to \mathcal{E}_s \to 0$, we get (by making tensor-products with $\mathbf{C}_s$) the exact sequence:

$$\mathbf{C}_s^p \xrightarrow{d(s)} \mathbf{C}_s^q \to E(s) \to 0 ,$$

which shows that d has constant rank in U. Thus Ker d and Im d are vector bundles, and we can write

$$\mathbf{C}_U^p = F_1 \oplus G_1 , \quad \mathbf{C}_U^q = F_0 \oplus G_0 ,$$

$$d : \begin{cases} F_1 \to 0 \\ G_1 \simeq F_0 . \end{cases}$$

Now $\mathscr{E} \simeq$ the sheaf of analytic sections of G_0, therefore $\mathscr{E}$ is locally free.

Definition 1: Let $\pi : X \to S$ be a finite morphism of analytic spaces, and $s \in S$. For each $x \in X(s) = \pi^{-1}(s)$, $\mathcal{O}_{X(s),x} = \mathbf{C} \otimes_{\mathcal{O}_{S,s}} \mathcal{O}_{X,x}$ is finite dimensional vectorspace over $\mathbf{C}$. Denote its dimension by $v(x)$. Then the degree $v(s)$ of s is defined by $v(s) = \sum_{x \varepsilon X(s)} v(x)$.

Theorem 1: Let $\pi : X \to S$ be a finite morphism of analytic space and let S be a reduced space. Then X is flat over S if and only if $v(s)$ is locally constant function of s.

Proof:
$$v(s) = \sum_{x \varepsilon X(s)} \dim_{\mathbf{C}} \mathcal{O}_{X(s),x} = \dim_{\mathbf{C}} \left(\bigoplus_{x \varepsilon X(s)} \mathcal{O}_{X(s),x} \right)$$

$$= \dim_{\mathbf{C}} \left(\bigoplus_{x \varepsilon X(s)} \left(\mathbf{C} \otimes_{\mathcal{O}_{S,s}} \mathcal{O}_{X,x} \right) \right)$$

$$= \dim_{\mathbf{C}} \mathbf{C} \otimes_{\mathcal{O}_{S,s}} \pi_*(\mathcal{O}_X)_s = \dim_{\mathbf{C}} E(s).$$

The theorem follows from propositions 1 and 2.

Examples of flat morphisms

Example 1: If $\pi : X \to S$ is a local isomorphism near x, then π is flat at x.

Example 2: Consider § 2, Ex. 1. Here $v(x) = 1$.

Examples of non-flat morphisms

Examples 1: If $X \subset S$ is a closed subspace, not open, $v(s)$ is not locally constant.

Example 2: Let X be a subspace of $\mathbf{C}^4$ defined by the ideal intersection of (x_3, x_4) and $(x_1 - x_1, x_4 - x_2)$ (which is equal to the product ideal) and let π be the projection onto the (x_1, x_2)-plane $\mathbf{C}^2$. Then X is a union of two 2-planes in $\mathbf{C}^4$, whose intersection is (0). When $s \neq 0$. $X(s)$ consists of two simple points, so $v(s) = 2$. $X(0)$ is given by the ideal $(x_1, x_2, x_3^2, x_3 x_4, x_4^2)$, thus $v(0) = 3$.

Example 3: Let $S = \{(u, v, w) \in \mathbf{C}^3 \mid v^2 = uw\}$ and $\pi : \mathbf{C}^2 \to S$ be the map $(x, y) \to (x^2, xy, y^2)$. This map identifies S with the quotient of $\mathbf{C}^2$ by the equivalence relation idenfying (x, y) with $(-x, -y)$. However, π is not flat, since for $s \in S$, $v(s) = 2$ if $s \neq 0$ and $v(s) = 3$ if $s = 0$.

B) *Projection of a product of analytic spaces*

Theorem 2 : Let S and X be analytic spaces. If $\pi : S \times X \to S$ is the projection morphism, then π is flat, i.e. $\mathcal{O}_{S \times X, '(s,x)}$ is a flat $\mathcal{O}_{S,s}$ module for every $(s, x) \in S \times X$.

To prove this theorem we need first some homological algebra. Then we shall show it in the particular case, when S is a manifold, and finally in the general case.

(a) *Koszul complex*

Let A be a ring, M an A-module and $h_1, ..., h_n$ homomorphisms $M \to M$, which commute with each other, i.e. $h_i h_j = h_j h_i$ for every i, j.

If $1 \leqq k \leqq n$, set $Q_k = M/h_1 (M) + ... + h_k (M)$, and $Q_0 = M$, thus, in particular, $Q_n = Q = M/ \sum\limits_{i=j}^{n} h_i (M),$. Every h_k induces a map $\tilde{h}_k \, Q_{k-1} \to Q_{k-1}$.

Definition 2 : The sequence $(h_1, ..., h_n)$ is called regular if each of the mappings $\tilde{h}_k$ $(1 \leqq k \leqq n)$ is injective.

The Koszul complex of the module M and of the mappings h_k $(1 \leqq k \leqq n)$ $K. = K. [M; h_1, ..., h_n]$ is defined in the following way:

$$K_i = \wedge^{n+i} A^n \otimes M \simeq M^{\binom{n}{i}} , \qquad 0 \leqslant i \leqslant n .$$

We define the homorphisms $d_i : K_i \to K_{i-1}$ $(i > 0)$ by $\lambda \otimes x \to \sum\limits_i (e_i \wedge \lambda) \otimes h_i (x),$ where (e_i) is the natural base of A^n. We also define $\varepsilon : K_0 \to Q$ as the natural map $: K_0 = M \to M/ \sum\limits_{i=1}^{n} h_i (M) = Q$. Using the fact that $h_1, ..., h_n$ commute with each other, it is easy to verify that

$$(d_{i-1} \circ d_i) (\lambda \otimes x) = \sum\limits_{i,j} (e_j \wedge e_i \wedge \lambda) \otimes h_j (h_i (x)) = 0;$$

also $\varepsilon d_1 = 0$. Thus $K.$ is really a complex.

Theorem 3 (Poincaré-Koszul).

If $(h_1, ..., h_n)$ is a regular sequence, then

$$H_i (K.) = \begin{cases} Q & if \quad i = 0 \\ \\ 0 & if \quad i > 0 \end{cases} .$$

If $h_i \in A$, it defines the map: $A \xrightarrow{h_i I} A$, which we denote also by h_i. We say that $(h_1, ..., h_n)$ is a regular sequence of elements if $(h_1 I, ..., h_n I)$ is a regular sequence.

Corollary. If $(h_1, ..., h_n)$ is a regular sequence of elements, then the Koszul complex $K. = K. [A; h_1, ..., h_n] = \{ \wedge^{n-1} A^n \simeq A^{\binom{n}{i}} \}$ is a free resolution of $Q = A/(h_i)$ ((h_i) is the ideal generated by $h_1, ..., h_n$)).

Example: If $A = C \{x_1, ..., x_n\}$; $h_i = x_i$, then $Q_k = A/(x_1, ..., x_k) = C \{x_{k+1}, ..., x_n\}$ and $Q = Q_n = C$. The complex $K. = K. [A; x_1, ..., x_n]$ is a free resolution of C.

(b) *Proof of theorem 2, when S is a complex manifold*

In this case we can take $\mathcal{O}_{S,s} = C \{t_1, ..., t_m\} = A$ and if $\mathcal{O}_{X,x} = C \{x_1, ..., x_n\}/(f_1, ..., f_p)$, then

$$\mathcal{O}_{S \times X, (s,x)} = C \{t_1, ..., t_m, x_1, ..., x_n\}/(f_1, ..., f_p) = B.$$

B is an A-module in a natural way.

By the corollary of the Poincaré-Koszul theorem $K. = K. [A; t_1, ..., t_m]$ in a free resolution of C. We want to compute the modules $\operatorname{Tor}_i^A (C, B) = H_i (K. \otimes B)$ ($i > 0$).

It's easily seen, that we can consider the complex $K. \otimes B$ as a Koszul complex $K'. = K. [B; t_1, ..., t_m]$ (where $t_i : B \xrightarrow{t_i I} B$). But now the sequence $(t_1, ..., t_m)$ is regular, thus by the Poincaré-Koszul theorem $H_i [K'.] = 0$ if $i > 0$.

In particular: $\operatorname{Tor}_1^A (C, B) = H_1 [K. \otimes B] = H_1 [K'.] = 0$. By the second flatness criterion B is A-flat.

(c) *The general case*

The question being local, we can suppose that $S \subset W \subset C^n$, where W is open, and S an analytic subspace of W. Let S be defined by $g_1, ..., g_r$. Then $S \times X \subset W \times X$ and $\mathcal{O}_S = \mathcal{O}_W/(g_1, ..., g_r)$. On the other hand $\mathcal{O}_{S \times X} = \mathcal{O}_{W \times X}/(g_1, ..., g_r) = \mathcal{O}_S \underset{\mathcal{O}_W}{\otimes} \mathcal{O}_{W \times X}$. The last equality follows from the fact, that if $\pi : X \to S$ is a morphism, and $S' \subset S$ a subspace, $X' = \pi^{-1} (S')$, then $\mathcal{O}_{X'} = \mathcal{O}_{S'} \underset{\mathcal{O}_S}{\otimes} \mathcal{O}_X$.

Remark : This a particular case of the following proposition: if π and π' are two morphisms of which at least one is finite, then

$$\begin{array}{ccc} X & & Y \\ {}_\pi\searrow & {}_S & \swarrow_{\pi'} \end{array} \qquad \mathcal{O}_{X\times Y \atop S} = \mathcal{O}_X \otimes_{\mathcal{O} \atop S} \mathcal{O}_Y .$$

We have proved that $\mathcal{O}_{W\times X}$ is $\mathcal{O}_W$-flat, so by scalar extension $\mathcal{O}_{S\times X}$ is $\mathcal{O}_S$ flat.

Corollary : If X and S are two manifolds and $\pi : X \to S$ is a submersion, then π is flat.

III. PRIVILEGED POLYCYLINDERS

§ 1. *Banach vector bundles over an analytic space*

Let E be a Banach space and X an analytic space. We denote then by E_X the trivial bundle $X \times E$ over X.

To define bundle morphisms, we first define the sheaf $\mathcal{H}_X(E)$ of germs of analytic morphisms from X to E. If $U \subset \mathbf{C}^n$ is open, then the set $\mathcal{H}(U, E)$ of analytic morphisms from U into E consists of all functions $g : U \to E$ having at every point $x \in U$ a converging power series expansion.

Let now X' be a local model for X, i.e. X' is the support of the quotient sheaf $\mathcal{O}_U/J$, where $U \subset \mathbf{C}^n$ is open and J is a coherent sheaf of ideals of $\mathcal{O}_U$, then $\mathcal{H}_{X'}(E)$ is the sheaf associated to the presheaf $V \to \mathcal{H}(V, E)/J_V \cdot \mathcal{H}(V, E)$ ($V \subset U$, V-open).

Remark : If X' is reduced, the sections of $\mathcal{H}_{X'}(E)$ are just the functions from X' to E which are locally induced by analytic functions on open sets in U.

The sheaf $\mathcal{H}_X(E)$ is constructed with help of the local models X' of X, i.e. $\mathcal{H}_X(E)|X' = \mathcal{H}_{X'}(E)$, for every local model X'.

Definition 1 : The set of *analytic morphisms* from an analytic space X into a Banach space E is the set $\mathcal{H}(X; E)$ of sections of the sheaf $\mathcal{H}_X(E)$.

Let $\mathcal{L}(E, F)$ be the Banach space of all continuous linear mappings from the Banach space E into the Banach space F.

Definition 2 : An *analytic vector bundle morphism* from E_X into F_X is an analytic morphism from X into $\mathcal{L}(E, F)$.

Let E be a topological space, X an analytic space, and $\pi : E \to X$ a continuous projection.
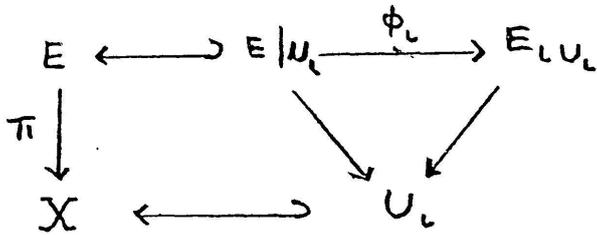

Suppose that X has an open covering $(U_\iota)_{\iota \in I}$, and that for every $\iota \in I$ there is given a trivial Banach space bundle $E_{\iota U_\iota}$ and a homeomosphism ϕ_ι, such that the following diagram is commutative:

We suppose further that for each pair $\iota, \kappa \in I$ there is given an analytic vector bundle morphism $\gamma_{\iota\kappa} : E_{\kappa U_\iota \cap U_\kappa} \to E_{\iota U_\iota \cap U_\kappa}$, with the underlying mapping $\phi_\iota \circ \phi_\kappa^{-1}$, such that:
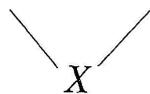

$$\gamma_{\iota\lambda} = \gamma_{\iota\kappa}\,\gamma_{\kappa\lambda}; \quad \gamma_{\iota\iota} = I, \quad \text{for all} \quad \iota, \kappa, \gamma \in I.$$

This data gives a Banach vector bundle atlas on E and provides E with the structure of a Banach vector bundle over X (two atlases are equivalent if there exists an atlas containing both).

Remark: If X is reduced, the $\gamma_{\iota\kappa}$ are determined by their underlying map and the condition $\gamma_{\iota\lambda} = \gamma_{\iota\kappa}\,\gamma_{\kappa\lambda}$ is automatically satisfied.

Using local triviality, we can define morphisms for general Banach vector bundles.

Proposition 1: Let $\phi : E \to F$ be a morphism of two Banach vector bundles E and F, and $x \in X$.

If $\phi_x \in \mathscr{L}(E(x), F(x))$ is an isomorphism, then there exists an open neighbourhood $U \subset X$ of x, such that $\phi|U : E|U \to F|U$ is a vector bundle isomorphism.

Proof: First we take a trivialisation $E|V = E_{0V}$, $F|V = F_{0V}$ at $x \in V \subset X$ (V-open).

The set $\operatorname{Isom}(E_0, F_0)$ of isomorphic mappings is an open subset of $\mathscr{L}(E_0, F_0)$ and the mapping $g \to q^{-1}$ is an analytic isomorphism:

$$\operatorname{Isom}(E_0, F_0) \simeq \operatorname{Isom}(F_0, E_0).$$

So we have in an open neighbourhood $U \subset X$ of x an analytic morphism $y \to \phi_y^{-1} \in \mathscr{L}(F_0, E_0)$, which defines the inverse morphism $(\phi|U)^{-1} : F|U \to E|U$.

Definition 3 : Let E and F be two Banach spaces and f a continuous linear mapping from E into F. f is a *split mono-(epi) morphism*, if there exists a mapping $g \in \mathcal{L}(F, E)$ such that $g \circ f = I_E$. (Resp. $f \circ g = I_F$.)

Definirion 4 : Let E_1 and E_2 be two Banach vector bundles over an analytic space X, and f a vector bundle morphism from E_1 into E_2. f *is a split mono (epi) morphism*, if there exists a vector bundle morphism $g : E_2 \to E_1$ such that $g \circ f = I_{E_1}$. (Resp. $f \circ g = I_{E_2}$.)

Equivalently, $f : E_1 \to E_2$ is a split monomorphism if an only if E_2 can

$$E_1 \underset{X}{\overset{}{\diagdown \diagup}} E_2$$
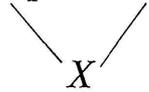

be decomposed in a direct sum $E_2 = F_2 \oplus G_2$ such that

$$f : \begin{cases} E_1 \simeq F_2 \\ \\ 0 \to G_2 \end{cases}.$$

and f is a split epimorphism if correspondingly

$$E_1 = F_1 \oplus G_1, \quad \text{such that} \quad f : \begin{cases} F_1 \to 0 \\ \\ G_1 \simeq E_2 \end{cases}.$$

Proposition 2 : Let $E \overset{\varphi}{\to} F$ be a bundle morphism and $x \in X$.

$$E \underset{X}{\overset{}{\diagdown \diagup}} F$$

If $\phi_x : E(x) \to F(x)$ is a split epi (mono) morphism, then the point x has an open neighbourhood $U \subset X$, such that $\phi | U : E | U \to F | U$ is a split vector bundle epi (mono) morphism.

Proof : Suppose that ϕ_x is a split epimorphism. We take first a trivilisation $E | V = E_{0V}$, $F | V = F_{0V}$ at x, so that there exists a mapping $\sigma \in \mathcal{L}(F_0, E_0)$, $\phi_x \circ \sigma = I_{F_0}$. If we define a morphism $\psi : F_{0V} \to E_{0V}$ by $x \to \sigma \in \mathcal{L}(F_0, E_0)$, the morphism $\gamma = \phi \circ \psi : F_{0V} \to F_{0V}$ has an isomorphic fibre mapping $\gamma_x = I_{F_0}$ in x. By proposition 1 we have an isomorphic restriction $\gamma | U$, $\phi | U \circ (\psi | U \circ (\gamma | U)^{-1}) = I_{F_{0U}}$.

When ϕ_x is a split monomorphism, the proof is similar.

Definition 5 : Let B_1, B_2, B_3 be Banach spaces, and $j, k : B_1 \overset{j}{\to} B_2 \overset{k}{\to} B_3$ continuous linear mappings. This sequence forms *a complex*, if $k \circ j = 0$. This sequence is *split exact* if the space B_i can be decomposed in direct

sums $B_i = C_i \oplus D_i$ such that

$$j : \begin{cases} C_1 \to 0 \\ \\ D_1 \simeq C_2 \end{cases} \qquad\qquad k : \begin{cases} C_2 \to 0 \\ \\ D_2 \simeq C_3 \end{cases}.$$

Definition 6 : A Banach vector bundle morphism sequence

$$E_1 \xrightarrow{\ f\ } E_2 \xrightarrow{\ g\ } E_3 \qquad \text{is } a \text{ complex if } g \circ f = 0.$$

with base X.

The sequence is *split exact*, if every E_i can be decomposed $E_i = F_i \oplus G_i$, such that:

$$f : \begin{cases} F_1 \to 0 \\ \\ G_1 \simeq F_2 \end{cases} \qquad\qquad g : \begin{cases} F_2 \to 0 \\ \\ G_2 \simeq F_3 \end{cases}.$$

Theorem 1 : Let $E_1 \xrightarrow{\ f\ } E_2 \xrightarrow{\ g\ } E_3$ be a complex of Banach vector bundles and $x_0 \in X$.

If the sequence of Banach spaces $E_1(x_0) \xrightarrow{f x_0} E_2(x_0) \xrightarrow{f x_0} E_3(x_0)$ is split exact, then there exists an open neighbourhood $U \subset X$ of x_0, such that $E_1|U \xrightarrow{f|U} E_2|U \xrightarrow{g|U} E_3|U$ is a split exact sequence of Banach vector bundles.

Proof : We take a neighbourhood V of x, such that we have a complex $E_{1V} \xrightarrow{f|V} E_{2V} \xrightarrow{g|V} E_{3V}$ of trivial bundles. By assumption we have the decompositions $E_{iV}(x_0) = F_i(x_0) \oplus G_i(x_0)$ with

$$f_{x_0} : \begin{cases} F_1(x_0) \to 0 \\ \\ G_1(x_0) \simeq F_2(x_0) \end{cases} \qquad\qquad g_{x_0} : \begin{cases} F_2(x_0) \to 0 \\ \\ G_2(x_0) \simeq F_3(x_0) \end{cases}.$$

By proposition 2, $f|V : G_{1V} \to E_{2V}$, $g|V : G_{2V} \to E_{3V}$ are both split monomorphisms in a neighbourhood $W \subset V$ of x_0 and the images $F_2 = f(G_{1W})$, $F_3 = g(G_{2W})$ are subbundles of E_{2W} esp. E_{3W}, such that

$$E_{2W} = F_2 \oplus G_{2W}, \qquad E_{3W} = F_3 \oplus G_{3W}.$$

By our construction

5

$$g \mid W : \begin{cases} F_2 & \to 0 \\ \\ G_2 \ W \simeq F_3 \end{cases}.$$

If $p : E_{2W} \to F_2$ is the projection with kernel G_{2W}, the map, $p \circ f : E_{1W} \to F_2$ is a split epimorphism in x_0. Again by prop. 2 we have over an open neighbourhood $U \subset W$ of x_0 a decomposition $E_{1U} = F_1 \oplus G_{1U}$ (with $F_1 = \mathrm{Ker}\, p \circ f$)

$$(p \circ f) \mid U : \begin{cases} F_1 & \to 0 \\ \\ G_{1U} \overset{\sim}{\to} F_{2U} \end{cases}.$$

The image $f \mid U\,(F_1)$ is contained in G_{2U}. But $g \mid U \circ f \mid U = 0$ and $g \mid G_{2U}$ is a monomorphism hence $f \mid U : F_1 \to 0$. We get finally (restricting all our morphisms to U)

$$f \mid U : \begin{cases} F_{1U} \to 0 \\ \\ G_{1U} \simeq F_{2U} \end{cases} \qquad g \mid U : \begin{cases} F_{2U} \to 0 \\ \\ G_{2U} \overset{\sim}{\to} F_{3U} \end{cases}.$$

§ 2. *Privileged polycylinders*

Definition 1 : A *polycylinder* in $\mathbf{C}^n$ is a compact set K of the form $K = K_1 \times \ldots \times K_n$ where each K_i is a compact, convex subset of $\mathbf{C}$, with nonempty interior. If each K_i is a disc, then K is a polydisc. We first recall the following theorem of Cartan.

Theorem 1 : Let K be a polycylinder contained in an open subset U of $\mathbf{C}^n$. Let $\mathscr{F}$ be a coherent analytic sheaf on U.

(A) There exists an open neighbourhood of K over which $\mathscr{F}$ admits a finite free resolution

$$0 \to \mathscr{L}_n \to \ldots \to \mathscr{L}_1 \to \mathscr{L}_0 \to \mathscr{F} \to 0 \,.$$

(B) $H^q(K, \mathscr{F}) = 0$ for $q > 0$.
   (Reference: For instance Gunning and Rossi.)
   We have the following consequences of this theorem:

1) Given a finite free resolution

$$0 \to \mathscr{L}_n \to \ldots \to \mathscr{L}_1 \to \mathscr{L}_0 \to \mathscr{F} \to 0$$

of a coherent sheaf $\mathscr{F}$, the sequence

$$0 \to \mathscr{L}_n(K) \to \ldots \to \mathscr{L}_0(K) \to \mathscr{F}(K) \to 0$$

is an $\mathcal{O}_U(K)$ - free resolution of $\mathscr{F}(K)$.

2) Given a short exact sequence of coherent sheaves

$$0 \to \mathscr{F}' \to \mathscr{F} \to \mathscr{F}'' \to 0,$$

then the sequence

$$0 \to \mathscr{F}_{\prime}(K) \to \mathscr{F}(K) \to \mathscr{F}''(K) \to 0 \quad \text{is exact.}$$

Let $\mathscr{F}$ be a coherent analytic sheaf on U, and let $K \subset U$ be a polycylinder If V is an open neighbourhood of K, then $\mathscr{F}(V)$ can be equipped with a Fréchet-space structure (see: Malgrange).

Hence we can give $\mathscr{F}(K)$ the structure of inductive limit of Fréchet-spaces. It is however essential for certain purposes to have Banach-spaces. This can be obtained by choosing a space slightly different from $\mathscr{F}(K)$ and by choosing K in a " privileged " way.

Let $B(K) = \{f : K \to \mathbf{C} \,|\, f \text{ continuous on } K \text{ and analytic on } \overset{\circ}{K}\}$, then $B(K)$ is Banach algebra and $B(K) \subset C(K)$. The sections of $\mathcal{O}_U$ over K are elements of $B(K)$, and $B(K)$ is in fact the uniform closure of $\mathcal{O}_U(K)$ in $C(K)$.

If $\mathscr{L} = \mathcal{O}_U^r$, we define $B(K, \mathscr{L}) = B(K)^r$. Then $B(K; \mathscr{L})$ is a free $B(K)$-module, and since $\mathscr{L}(K) = \mathcal{O}_U(K)^r$, we have $B(K; \mathscr{L}) = B(K) \underset{\mathcal{O}_{U(K)}}{\otimes} \mathscr{L}(K)$.

We now assume that $\mathscr{F}$ is a coherent sheaf on U, where $U \subset \mathbf{C}^n$ is open. Consider a free resolution

$$(R) \qquad 0 \to \mathscr{L}_n \to \ldots \to \mathscr{L}_1 \to \mathscr{L}_0 \to \mathscr{F} \to 0 \quad \text{of } \mathscr{F}.$$

From (R) we get an $\mathcal{O}_U(K)$-free resolution of $\mathscr{F}(K)$

$$(R') \qquad 0 \to \mathscr{L}_n(K) \to \ldots \to \to_1(K) \to \mathscr{L}_0(K) \to \mathscr{F}(K) \to 0.$$

Taking the tensorproduct $B(K) \underset{\mathcal{O}_{U}(K)}{\otimes}$ we get the complex

$$B(K; \mathscr{L}.) : 0 \to B(K; \mathscr{L}_n) \to \ldots \to B(K; \mathscr{L}_1) \to B(K; \mathscr{L}_0).$$

Definition 2 : The polycylinder K is called $\mathscr{F}$-*privileged* if the complex $B(K; \mathscr{L}.)$ is split-exact in every degree > 0.

Remark : The property of being $\mathscr{F}$-privileged is independent of the resolution (R).

The exactnes of $B(K; \mathscr{L})$ can be expressed by $\operatorname{Tor}_i^{\mathcal{O}(K)}(B(K), \mathscr{F}(K)) = 0$, for every $i > 0$, and Tor is independent of the resolution (R). It is a little

more complicated to show, that the splitting property is independent of (R), and this is omitted.

Since $B(K; \mathscr{L}_i)$ is a Banach space, the image and its complement are thus Banach spaces if K. is $\mathscr{F}$-privileged. In this case we define $B(K; \mathscr{F}) = {} = \mathrm{Coker}\,(B(K, \mathscr{L}_1) \to B(K; \mathscr{L}_0)) = B(K) \otimes_{\mathcal{O}_U} \mathscr{F}(K)$ and we get a $B(K)$-module, which is a Banach-space.

Warning: In the definition of split-exactnes, the subspaces are splitting vector spaces, but they are not splitting $B(K)$-modules in general.

We have the following important theorem about the existence of privileged polycylinders:

Theorem 2: Let U be an open subset of $\mathbf{C}^n$, and let $\mathscr{F}$ be a coherent analytic sheaf on U. For any $x \in U$ there exists a fundamental system of neighbourhoods of x in U, which are $\mathscr{F}$-privileged polycylinders.

For the proof, see Douady: § 7, 4, th 1.

Example: (Curves in $\mathbf{C}^2$)   Let $U \subset \mathbf{C}^2$ be an open connected neighbourhood of the origin, and let $h: U \to \mathbf{C}$ be analytic and $h \neq 0$.

Let X be the curve given by h, that is $X = h^{-1}(0)$, $\mathcal{O}_X = \mathcal{O}_U/(h)$. We have an exact sequence $0 \to \mathcal{O}_U \xrightarrow{h.I} \mathcal{O}_U \to \mathcal{O}_X \to 0$. Consider a polycylinder $K = K_1 \times K_2 \subset U$. By definition K is $\mathcal{O}_X$-priviledged if and only if $h: B(K) \to B(K)$ is a split monomorphism.

Let $\dot{K}_j$ denote the boundary of K_j, and define $\ddot{K} = \dot{K}_1 \times \dot{K}_2$ ($\ddot{K}$ is called the Šilov Boundary of K).

Proposition 1: (a) The following conditions are equivalent:
(i) $h: B(K) \to B(K)$ is a monomorphism.
(i') $\exists\, a > 0$ such that $\|hf\| \geqq a\|f\|$, $\forall f \in B(K)$.

(ii) $X \cap \ddot{K} = \varnothing$.

(b) If $(\dot{K}_1 \times \dot{K}_2) \cap X = \varnothing$, then h is a split monomorphism (i.e. K is $\mathcal{O}_X$ privileged).

Proof: (a) (i) $\Leftrightarrow$ (i') is a well known fact from the theory of normed vector spaces.

(ii) $\Rightarrow$ (i').   Assume $X \cap \ddot{K} = \varnothing$. If $f \in B(K)$, then it follows from the maximum principle that $\|f\| = \sup_{K} |f(x)| = \sup_{\ddot{K}} |f(x)|$. Since $h(x) \neq 0$

whenever $x \in \overset{..}{K}$, we get $a = \inf_K |h(x)| > 0$. Hence $||hf|| = \sup_K |hf(x)| \geqq$

$\geqq a \sup_K |f(x)| = a \, ||f||$.

(i') $\Rightarrow$ (ii). Suppose that $X \cap \overset{..}{K} \neq \varnothing$ and $x = (x_1, x_2) \in X \cap \overset{..}{K}$. We choose an analytic function $f_1 : U_1 \to \mathbf{C}$, where $U_1 \supset K_1$, and U_1 is open, such that $f_1(x_1) = 1$, $|f_1(z)| < 1$ if $z \in K_1$, $z \neq x_1$. Similarly we choose an analytic function $f_2 : U_2 \to \mathbf{C}$, with the same properties. Consider the function $f \in B(K) : (z_1, z_2) \to f_1(z_1) f_2(z_2)$. Since $h(x) = 0$ it follows that the sequence $\{hf^n\}$ converges pointwise to 0 in K.

Applying Dini's theorem we get $||hf^n|| \to 0$. From the inequality $a \, ||f^n|| \leqq$ $\leqq ||hf^n||$ we get $||f^n|| \to 0$, which is a contradiction, because for every $n : f^n(x) = 1$.

(b) Use the Weierstrass preparation theorem (extended form).

Question. Does the condition (ii) imply that $h : B(K) \to B(K)$ is a split monomorphism?

IV. FLATNESS AND PRIVILEGE

§ 1. *Morphisms from an analytic space into $B(K)$*

Let S be an analytic space and K a polycylinder in an open set $U \subset \mathbf{C}^n$. We want to construct an $\mathcal{O}_S$-algebra homomorphism $\phi : \mathcal{O}_{S \times U}(S \times U) \to$ $\to \mathscr{H}(S; B(K))$.

(a) Consider first $S = U' \subset \mathbf{C}^m$, U'-open. If $h \in \mathcal{O}_{U' \times U}(U' \times U)$ and $s \in U'$, $x \in K$, define $(\phi(h)(s))(x) = h(s,x)$. Using the Cauchy integral, one can show that $\phi(h)$ is analytic. On the other hand its obvious that ϕ is an $\mathcal{O}_{U'}$-algebra homomorphism.

(b) Let S have a special model in the polydisc Δ in $\mathbf{C}^m$, defined by a sheaf $\mathscr{I}$ of ideals of $\mathcal{O}_\Delta$, and let $\mathscr{I}$ be generated by $f_1, ..., f_p$, V-a polycylinder neighbourhood of K in U. By Cartan's theorem B for a polycylinder,

the sequence $0 \to \mathscr{I}(\Delta \times V) \to \mathcal{O}(\Delta \times V) \overset{\pi}{\to} \mathcal{O}(S \times V) \to 0$ is exact. If we denote

by $\tilde{\pi}$ the projection $\mathscr{H}(\Delta, B(K)) \to \mathscr{H}(S, B(K))$, $(f_1, ..., f_p) \cdot \mathscr{H}(\Delta, B(K)) \subset$

$\subset \mathrm{Ker}\, \tilde{\pi}$. Therefore, because $\tilde{\pi}$ is surjection, there exists a unique

$\phi : \mathcal{O}(S \times V) \to \mathscr{H}(S, B(K))$, such that the diagram

$$\mathcal{O}(\Delta \times V) \overset{\phi}{\to} \mathcal{H}(\Delta, B(K))$$

$$\pi \downarrow \qquad = \qquad \downarrow \tilde{\pi}$$

$$\mathcal{O}(S \times V) \overset{\phi}{\to} \mathcal{H}(S, B(K))$$

is commutative; ϕ is evidently an $\mathcal{O}_S$-algebra homomorphism.

§ 2. The flatness and privilege theorem

Notation

Let S be an analytic space, U an open set in $\mathbf{C}^n$, and $\pi : S \times U \to S$ the first projection.

If $\mathcal{F}$ is an $\mathcal{O}_{S \times U}$ module, then for every $s \in S$ we denote by $\mathcal{F}(s)$ the $\mathcal{O}_U$-module $i_s^* \mathcal{F}$, where i_s is the injective morphism $x \to (s, x)$ from U into $S \times U$. If $x \in U$

$$(\mathcal{F}(s))_x \simeq \mathcal{F}_{(s, x)}/m_s \cdot \mathcal{F}_{(s, x)} \simeq \mathcal{F}_{(s, x)} \otimes_{\mathcal{O}_{S,s}} \mathbf{C}_s .$$

Theorem 1 : Let $\mathcal{E}$ be a coherent and S-flat $\mathcal{O}_{S \times U}$-module, and K a polycylinder in U.

(a) When K is privileged for $\mathcal{E}(s_0)$, s_0 has a neighbourhood V such that K is $\mathcal{E}(s)$-privileged for each $s \in V$. In other words: the set $S' = \{s \in S \mid K$ is $\mathcal{E}(s)$-privileged$\}$ is open in S.

(b) It is possible to define a Banach vector bundle over S' whose fibre at any $s \in S'$ is $B(K, \mathcal{E}(s))$.

To prove the theorem we need:

Lemma 1 : Under the conditions of the theorem, we can, for every $s \in S$, find a neighbourhood W of $\{s\} \times K$ and a free resolution of finite length

$$0 \to \mathcal{L}_p \overset{d_p}{\to} \ldots \overset{d_2}{\to} \mathcal{L}_1 \overset{d_1}{\to} \mathcal{L}_0 \overset{\varepsilon}{\to} \mathcal{E} \to 0 \text{ in } W.$$

Proof : Let (s, x) be a point of $S \times U$ and $\mathcal{L}_*^0$ a finite resolution of $\mathcal{F}(x)$ in a neighbourhood of x (there exists such one, by the theorem of syzygies). We shall show that that there exists a resolutin $\mathcal{L}^*$ of $\mathcal{F}$ in a neighbourhood of (s, x) such that $\mathcal{L}^*(s) = \mathcal{L}_*^0$; if $\mathcal{L}_i^0 = \mathcal{O}_x^{r_i}$ define

$$\mathcal{L}_i = \mathcal{O}_{S \times U}^{r_i} \text{ and } \mathcal{K}_i^0 = \text{Ker } d_i^0 \colon \mathcal{L}_i^0 \to \mathcal{L}_{i-1}^0.$$

We shall construct by induction (with respect to i) $d_i : \mathscr{L}_1 \to \mathscr{L}_{i-1}$ in a neighbourhood of (s, x) such that $d_i(s) = d_i^0$, and prove that $\mathscr{K}_i = \mathrm{Ker}\, d_i$ is S-flat and that $\mathscr{K}_i(s) = \mathscr{K}_i^0$.

$$
\begin{array}{ccc}
\mathscr{L}_{i+1} & \xrightarrow{\ d_{i+1}\ } & \mathscr{K}_i \\
\downarrow & & \downarrow \\
\mathscr{L}_{i+1}^0 & \xrightarrow{\ d_{i+1}\ } & \mathscr{K}_i^0
\end{array}
$$

Suppose that we have constructed d_i and proved the properties for $\mathscr{K}_i$. We can construct $d_{i+1} : \mathscr{L}_{i+1} \to \mathscr{L}_i$ in a neighbourhood of (s, x) such that the diagram is commutative.

Nakayama's lemma shows that $\mathrm{Im}\, d_{i+1} = \mathscr{K}_i$ at the point (s, x), therefore in a neighbourhood of that point.

The exact sequence

$$
0 \to \mathscr{K}_{i+1} \to \mathscr{L}_{i+1} \to \mathscr{K}_i \to 0 ,
$$

where $\mathscr{K}_i$ and $\mathscr{L}_{i+1}$ are S-flat, shows that $\mathscr{K}_{i+1}$ is S-flat, and that $\mathscr{K}_{i+1}(s) = \mathscr{K}_{i+1}^0$. The first step of the induction is analogous.

Proof of the theorem : Let $s_0 \in S$ and

$$
0 \to \mathscr{L}_p \xrightarrow{\ d_p\ } \ldots \to \mathscr{L}_0 \xrightarrow{\ d_1\ } \mathscr{E}|W \to 0
$$

be a free $\mathcal{O}_{S \times U}$ resolution of $\mathscr{E}$ in a neighbourhood $W = V_1 \times V_2$ of $\{s_0\} \times K$. The sheaf $\mathscr{E}$ is $\mathcal{O}_S$-flat, so for each $s \in V_1$, the sequence

$$
0 \to \mathscr{L}_p \otimes_{\mathcal{O}_{S|V_1}} \mathbf{C}_s \to \ldots \to \mathscr{L}_1 \otimes_{\mathcal{O}_{S|V_1}} \mathbf{C}_s \to \mathscr{L}_0 \otimes_{\mathcal{O}_{S|V_1}} \mathbf{C}_s \to \mathscr{E}_{|W} \otimes_{\mathcal{O}_{S|V_1}} \mathbf{C}_s \to 0
$$

is exact. So the sequence

$$
(A) \qquad 0 \to \mathscr{L}_p(s) \xrightarrow{\ d_p(s)\ } \ldots \to \mathscr{L}_1(s) \xrightarrow{\ d_1(s)\ } \mathscr{L}_0(s) \xrightarrow{\ \varepsilon(s)\ } \mathscr{E}(s)_{|V_2} \to 0
$$

is exact when $s \in V_1$. Now $\mathscr{L}_i(s) \simeq \mathcal{O}_{V_2}^{r_i}$ $(0 \leq i \leq p)$ and every $d_i(s)$ induces a continuous linear map:

$B(K, \mathscr{L}_i(s)) \to B(K, \mathscr{L}_{i-1}(s))$, which we also denote by $d_i(s)$. We can consider $d_i = (d_{ijk})$ as an $r_i \times r_{i-1}$-matrix with entries from $\mathcal{O}_{S \times U}(W)$.

By § 1 we have a $\mathcal{O}_S$-algebra homomorphism

$$
\mathcal{O}_{S \times W}(S \times W) \to \mathscr{H}(S, B(K)) .
$$

From the matrix (d_{ijk}) we get by this homomorphism a morphism $\tilde{d}_i$:

$$
V_0 \to \mathscr{L}(B(K)^{r_i}, B(K)^{r_{i-1}}) = \mathscr{L}(B(K, \mathscr{L}_i(s)), B(K, \mathscr{L}_{i-1}(s))).
$$

(Here V_0 is some neighbourhood of s_0) such that $\tilde{d}_i(s) = d_i(s)$ for each $s \in V_0$. In other words we have a sequence of Banach vector bundle morphisms

$$(B) \qquad 0 \to B(K, \mathscr{L}_p) \xrightarrow{d_p} \ldots \xrightarrow{\tilde{d}_1} B(K, \mathscr{L}_0).$$

Using the fact that $\mathscr{O}_{S \times U}(S \times U) \to \mathscr{H}(S, B(K))$ is an $\mathscr{O}_S$-algebra homomorphism, it easily follows that (B) is complex of Banach vector bundles over S.

Now K is $\mathscr{E}(s_0)$-privileged, thus

$$0 \to B(K, \mathscr{L}_p(s_0)) \xrightarrow{d_p(s_0)} \ldots \xrightarrow{d_1(s_0)} B(K, \mathscr{L}_0(s_0))$$

is split exact, so by theorem III.1

$$0 \to B(K, \mathscr{L}_p)_{|V} \xrightarrow{\tilde{d}_p|V} \ldots \xrightarrow{\tilde{d}_i|V} B(K, \mathscr{L}_0)_{|V}$$

is split exact for some neighbourhood V of s_0.

Because $\tilde{d}_i(s) = d_i(s)$ and the sequence (A) is exact part (a) of the theorem follows.

(b) $B(K. \mathscr{L}_0)|V$ splits as the direct sum of im $\tilde{d}_1$ and a bundle E_V, such that $E_{V,s} \simeq B(K, \mathscr{E}(s))$, for each $s \in V$. We must show that these bundle structures fit together globally.

Suppose therefore that V is open in S' and that

$$0 \to \mathscr{L}_p \xrightarrow{d_p} \ldots \xrightarrow{d_2} \mathscr{L}_1 \xrightarrow{d_1} \mathscr{L}_0 \to \mathscr{E}_{|V \times V_2} \to 0$$

$$0 \to \mathscr{L}'_p \xrightarrow{d'_p} \ldots \xrightarrow{d'_2} \mathscr{L}'_1 \xrightarrow{d'_1} \mathscr{L}'_0 \to \mathscr{E}_{|V \times V_2} \to 0$$

are free resolutions of ξ over $V \times V_2$.

If V_1, V_2 are open polycylinders, we can find an $\mathscr{O}_{S \times U}$-homomorphism $\phi_0 : \mathscr{L}_0 \to \mathscr{L}'_0$ such that

$$\mathscr{L}'_0 \xrightarrow{\varepsilon'} \mathscr{E}_{|V \times V_2} \to 0$$

$$\phi_0 \uparrow \qquad \|$$

$$\mathscr{L}_0 \xrightarrow{\varepsilon} \mathscr{E}_{|V \times V_2} \to 0$$

commutes. ϕ_0 determines a bundle morphism $\tilde{\phi}_0 : B(K, \mathcal{L}_0) \to B(K, \mathcal{L}'_0)$.
$B(K, \mathcal{L}_0)$ (resp. $B(K, \mathcal{L}'_0)$) splits as $(\text{im } \tilde{d}_1) \otimes E_V$ [Resp. $(\text{im } \tilde{d}'_1) \otimes E'_V$].

Let p' be the projection morphism: $B(K, \mathcal{L}_0) \to E'_V$ with kernel im $\tilde{d}'_1$,
and put $\tilde{\phi} = p' \circ \phi_0 | E_V$.

The commutative diagram

and the open mapping theorem shows that $\tilde{\phi}(s)$ is an isomorphism of
Banach spaces for each $s \in V$, so $\tilde{\phi} : E_V \to E'_V$ is a bundle isomorphism. We
also notice that $\tilde{\phi}$ depends only on the choice of splittings in $B(K, \mathcal{L}_0)$ and
$B(K, \mathcal{L}'_0)$, and not on the choice of $\tilde{\phi}_0$. This ends the proof of the theorem.

Remark : Consider the general situation where X and S are analytic
spaces, and $\pi : X \to S$ is a morphism, $\mathscr{E}$ an $\mathcal{O}_X$-module. To study the local
dependence of $\mathscr{E}$ on S, one can imbed an open set X' in X in
the open set $U \subset \mathbf{C}^n$. The morphism $\phi : X' \to U, \pi : X' \to S$ deter-
mine the imbedding $\pi \times \phi : X' \to S \times U$ such that the diagram

commutes. $\mathscr{E}$ can be extended by zero into a sheaf $\mathscr{E}'$ over $U \times S$. Obviously
this sheaf $\mathscr{E}'$ is S-flat iff $\mathscr{E}$ is S-flat.

Therefore theorem 1 makes clear also this general situation.

Corollary : If $\pi : X \to S$ is a morphism and $\mathscr{E}$ a coherent $\mathcal{O}_X$-module.
Then $\pi \,|\, \text{Supp}(\mathscr{E})$ is an open map.

Proof : Suppose as above that X is imbedded in $S \times U$, and $\mathscr{E}$ in extended
by zero to $S \times U$. Let $x_0 \in \text{Supp } \mathscr{E}$, and V be a neighbourhood of x_0 in $S \times U$.
Let $s_0 = \pi(x_0)$ and choose an $\mathscr{E}(s_0)$-privileged polycylinder K in U, such
that $\{s_0\} \times K \subset V$, over some neighbourhood W of s_0. We have the Banach
bundle $B(K, \mathscr{E}|\pi^{-1}(W))$, whose fiber over s is $B(K, \mathscr{E}(s))$. Since
$x_0 \in \text{Supp } \mathscr{E}(s_0)$ and K is a neighbourhood of x_0, $B(K; \mathscr{E}(s_0)) \neq 0$. As all
the fibers are isomorphic, then for all $s \in U$, $B(K; \mathscr{E}(s)) \neq 0$ and therefore
$\{s\} \times K \cap \text{Supp } \mathscr{E} \neq 0$, and $s \in \pi(\text{Supp } \mathscr{E})$. This proves that π is open.
