expansion. Let ω be the canonical invariant differential on E and write $\omega/dZ = \sum_{i=0}^{\infty} C_i Z^i$. It is an immediate consequence of Honda's theorem that $f_p \equiv C_{p-1} \pmod{p}$.

COROLLARY 1.2. Let E be an elliptic curve, and assume that E has bad reduction at a prime p . Then

- (1) $C_{p-1} \equiv 0, 1, -1 \pmod{p}$.
- (2) E has additive reduction at $p < = > C_{p-1} \equiv 0 \pmod{p}$.
- (3) For $p > 2$, E has split multiplicative reduction at $p < = > C_{p-1} \equiv 1 \pmod{p}$.
- (4) For $p > 2$, E has non-split multiplicative reduction at $p < = > C_{p-1} \equiv -1 \pmod{p}$.

Proof: Since $C_{p-1} \equiv f_p \pmod{p}$ and $f_p = 0, 1$, or -1 , the congruence class of C_{p-1} modulo p determines the reduction type uniquely as indicated except for $p = 2$.

From now on we shall assume that all curves and points are defined over \mathbf{Q} , and that all Weierstrass equations are minimal. We wish to derive some simple arithmetical criteria for determining which of the three types of reduction occurs at a given prime p where E has bad reduction. From now on we shall assume that E has bad reduction at the prime p under discussion.

§2. THE CASE $p = 2$

For a curve given in the form (1.2), we have

$$(2.1) \quad \omega = dX/(2Y + a_1X + a_3)$$

Expressing X and Y in terms of Z and computing (cf. Tate [5] for the details), one obtains

$$(2.2) \quad C_1 = a_1$$

THEOREM 2.1. Assume E has bad reduction at 2.

- (1) E has additive reduction at $2 < = > a_1 \equiv 0 \pmod{2} < = > c_4 \equiv 0 \pmod{2}$.
- (2) E has split multiplicative reduction at $2 < = > a_1 \equiv 1 \pmod{2}$ and $a_2 + a_3 \equiv 0 \pmod{2}$.

(3) E has non-split multiplicative reduction at 2 $\Leftrightarrow a_1 \equiv 1 \pmod{2}$ and $a_2 + a_3 \equiv 1 \pmod{2}$.

Proof: (1). $c_4 \equiv b_2^2 - 24b_4 \equiv b_2^2 \equiv b_2 \equiv a_1^2 + 4a_2 \equiv a_1^2 \equiv a_1 \equiv C_1 \pmod{2}$. Now apply Corollary 1.2, part (2).

(2) and (3). By Corollary 1.2, part (2), we have multiplicative reduction $\Leftrightarrow a_1 \equiv 1 \pmod{2}$. Assume that this is so. Let $S = (x, y)$ be the singular point. Let

$$(2.3) \quad H = Y^2 + a_1XY + a_3Y - X^3 - a_2X^2 - a_4X - a_6$$

Compute in $\mathbf{Z}/2\mathbf{Z}$ for the remainder of the proof.

$$(2.4) \quad \frac{\partial H}{\partial X} = a_1Y - 3X^2 - 2a_2X - a_4 = Y + X^2 + a_4$$

$$(2.5) \quad \frac{\partial H}{\partial Y} = 2Y + a_1X + a_3 = X + a_3$$

$x = a_3$ from (2.5) and $y = x^2 + a_4 = x + a_4 = a_3 + a_4$ from (2.4). Transform S to $(0, 0)$ via $X \rightarrow X + a_3$ and $Y \rightarrow Y + a_3 + a_4$. We obtain

$$\begin{aligned} H &= (Y+a_3+a_4)^2 + a_1(X+a_3)(Y+a_3+a_4) + a_3(Y+a_3+a_4) \\ &\quad - (X+a_3)^3 - a_2(X+a_3)^2 - a_4(X+a_3) - a_6 \\ &= Y^2 + XY + X^3 + (a_2 + a_3)X^2 \end{aligned}$$

The tangents at $(0, 0)$ are given by $Y^2 + XY + (a_2 + a_3)X^2 = 0$. E has split multiplicative reduction at 2 \Leftrightarrow this form is reducible over $\mathbf{Z}/2\mathbf{Z} \Leftrightarrow a_2 + a_3 \equiv 0 \pmod{2}$.

§3. THE CASE $p = 3$

As in §2, a short computation (again see Tate [5] for the details) yields

$$(3.1) \quad C_2 = a_1^2 + a_2$$

THEOREM 3.1. Assume E has bad reduction at 3.

- (1) E has additive reduction at 3 $\Leftrightarrow a_1^2 + a_2 \equiv 0 \pmod{3} \Leftrightarrow c_4 \equiv 0 \pmod{3}$.
- (2) E has multiplicative reduction at 3 $\Leftrightarrow a_1^2 + a_2 \not\equiv 0 \pmod{3} \Leftrightarrow c_4 \not\equiv 0 \pmod{3}$.
