5. THE LINE-SPHERE TRANSFORMATION

The homogeneous contact manifold of co-directions in complex projective space P^3 , obtained from the simple complex Lie algebra of type A_3 , must coincide with that of oriented co-directions in complex Euclidean space E^3 , obtained from the algebra of type D_3 , in view of the isomorphisms $A_3 \simeq D_3$. To exhibit this explicitly, we introduce a third homogeneous contact manifold in terms of which both of these can be conveniently described, namely, the space of lines in the quadric Ω^4 in P^5 of Section 1.

5.1. We carry out the construction of 2.10 for the simple complex Lie algebras of type B_l and D_l , making the restriction to type D_3 later.

Let $\mathfrak{g} = \mathfrak{o}(A; \mathbb{C})$, complex square matrices X for which ${}^tXA + AX = 0$, where

$$A = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 0 & 1_l \\ 0 & 1_l & 0 \end{bmatrix} \quad \text{in case } B_l$$

or

$$A = \begin{bmatrix} 0 & 1_l \\ 1_l & 0 \end{bmatrix} \quad \text{in case } D_l,$$

that is, the quadratic form defining \mathfrak{g} is

$$\xi_0^2 + 2\xi_1\xi_{l+1} + \dots + 2\xi_l\xi_{2l}$$

or

$$2\xi_1\xi_{l+1} + \dots + 2\xi_l\xi_{2l}$$

respectively [4, (16.3) and (16.4)].

We exhibit the details of the construction for the case of D_l . For B_l one need only carry along an additional initial row and column in the matrices, as well as the corresponding roots; the conclusions are the same.

Thus \mathfrak{g} consists of $2l$ by $2l$ matrices of the form

$$\begin{bmatrix} X_1 & X_2 \\ X_3 & -{}^tX_1 \end{bmatrix},$$

where X_1 is l by l and arbitrary and X_2 and X_3 are l by l and skew-symmetric. For Cartan subalgebra \mathfrak{h} of \mathfrak{g} take diagonal matrices H of the form

$$H = \text{diag} (h_1, \dots, h_l \mid -h_1, \dots, -h_l).$$

Let $\delta_i, i = 1, 2, \dots, l$ be the linear function on \mathfrak{h} which assigns h_i to $H: \delta_i(H) = h_i$. The roots of \mathfrak{g} with respect to \mathfrak{h} are

$$\begin{aligned} \pm \delta_i \pm \delta_j \quad i, j = 1, 2, \dots, l \\ \text{and } i \neq j \end{aligned}$$

and the root vector E_α corresponding to the root α is

$$\begin{aligned} E_{\delta_i - \delta_j} &= \begin{bmatrix} E_{ij} & 0 \\ 0 & -E_{ji} \end{bmatrix}, \quad i \neq j, \\ E_{\delta_i + \delta_j} &= \begin{bmatrix} 0 & E_{ij} - E_{ji} \\ 0 & 0 \end{bmatrix}, \quad i < j, \\ E_{-\delta_i - \delta_j} &= \begin{bmatrix} 0 & 0 \\ E_{ji} - E_{ij} & 0 \end{bmatrix}, \quad i < j, \end{aligned}$$

where E_{ij} is the l by l matrix with 1 in the i^{th} row and j^{th} column and 0s elsewhere [4, (16.3)]. A system of simple roots is

$$\delta_1 - \delta_2, \delta_2 - \delta_3, \dots, \delta_{l-1} - \delta_l, \quad \text{and} \quad -\delta_1 - \delta_2,$$

(this is not the same choice as in [4, (16.3)]), for which the maximal root is

$$\rho = -\delta_{l-1} - \delta_l,$$

[4, App., Table E]. The Killing form of \mathfrak{g} is $\langle X, Y \rangle = (2l-2) \text{tr}(XY)$, but we replace this with $\langle X, Y \rangle = \frac{1}{2} \text{tr}(XY)$ for convenience. Then the H_α in \mathfrak{h} are given by

$$H_{\pm\delta_i \pm \delta_j} = \text{diag}(0, \dots, 0, \pm 1, 0, \dots, 0, \pm 1, 0, \dots, 0 \mid \text{---}),$$

where the ± 1 s occur in the i^{th} and j^{th} entries and the second l entries are the negatives of the first l entries. Especially,

$$H_\rho = \text{diag}(0, \dots, 0, -1, -1 \mid 0, \dots, 0, 1, 1).$$

It is now straightforward to determine for which roots α we have $\langle H_\rho, H_\alpha \rangle \geq 0$ and find that \mathfrak{p} in (i) of 2.9 consists of matrices of the form

$$\left[\begin{array}{c|ccc} & \text{arbitrary} & 0 & 0 \\ & (l-2) \text{ by } (l-2) & \vdots & \vdots \\ & \text{skew-} & & \\ & \text{symmetric} & 0 & 0 \\ & 0 \text{ -----} & 0 & 0 & 0 \\ & 0 \text{ -----} & 0 & 0 & 0 \\ \hline & * \text{ -----} & * & 0 & 0 \\ & \vdots & \vdots & \vdots & \vdots \\ & \text{arbitrary} & & 0 & 0 \\ & l \text{ by } l & & * & * \\ & \text{skew-} & & & \\ & \text{symmetric} & & * & * \\ & * \text{ -----} & * & * & * \end{array} \right],$$

where the starred entries are arbitrary.

5.2. The connected centerless simple group $G = PSO(A; \mathbb{C})$ is transitive on the lines of the quadric Ω^{2l-2}

$$\xi_1 \xi_{l+1} + \dots + \xi_l \xi_{2l} = 0$$

in P^{2l-1} by Witt's theorem. The Lie algebra of the isotropy subgroup of the line l_0 joining

$${}^t(0, \dots, 0, 1, 0) \quad \text{and} \quad {}^t(0, \dots, 0, 0, 1)$$

is \mathfrak{p} . Hence

$$G/P = \text{space of lines in } \Omega^{2l-2}.$$

The element $W = E_\rho$ of \mathfrak{p} giving the contact structure on G/P , as in 2.7, is

$$W = \left[\begin{array}{c|ccc} & 0 & & 0 \\ & & & \\ \hline & 0 & & \\ & & & 0 \\ & 0 & -1 & \\ & 1 & 0 & \end{array} \right]$$

In general, the construction of 2.10 gives the $(2n-1)$ -dimensional homogeneous contact manifold of lines in the quadric Ω^{n+1} in P^{n+2} , where Ω^{n+1} is

$$\xi_0^2 + 2\xi_1 \xi_{l+1} + \dots + 2\xi_l \xi_{2l} = 0$$

in case B_l when n is even, $n+3 = 2l+1$, and Ω^{n+1} is Ω^{2l-2} above in case D_l when n is odd, $n+3 = 2l$; $n \geq 2$.

The real contact structure on the $(2n-1)$ dimensional space of lines of Ω^{n+1} in real projective space P^{n+2} is described by viewing all quantities in the foregoing discussion as being real. Especially, G_0 of 2.11 is the one- or two- component centerless group $PSO(A; \mathbf{R})$ consisting of real contact automorphisms.

5.3. The line joining $x = {}^t(x_0, x_1, x_2, x_3)$ and $y = {}^t(y_0, y_1, y_2, y_3)$ in complex projective space P^3 has Plücker coordinates $p_{ij} = x_i y_j - x_j y_i$. These coordinates are the coefficients of the bivector $x \wedge y$ with respect to the basis

$$e_1 \wedge e_2, e_3 \wedge e_1, e_2 \wedge e_3, e_0 \wedge e_3, e_0 \wedge e_2, e_0 \wedge e_1,$$

where $e_0 = {}^t(1, 0, 0, 0), \dots, e_3 = {}^t(0, 0, 0, 1)$, and satisfy

$$p_{01} p_{23} + p_{02} p_{31} + p_{03} p_{12} = 0,$$

[6, §69]. If we set

$$\begin{aligned} \xi_1 &= p_{12}, & \xi_2 &= p_{31}, & \xi_3 &= p_{23}, \\ \xi_4 &= p_{03}, & \xi_5 &= p_{02}, & \xi_6 &= p_{01}, \end{aligned}$$

we have that the lines of P^3 correspond to the points of the quadric Ω^4

$$\xi_1 \xi_4 + \xi_2 \xi_5 + \xi_3 \xi_6 = 0$$

in P^5 . Two lines of P^3 intersect exactly when their corresponding points on Ω^4 are conjugate, that is, the line joining these points lies entirely in Ω^4 .

To a point x in P^3 we associate all lines of P^3 incident with x and hence a plane lying in Ω^4 . To a plane u in P^3 we associated all lines of P^3 lying in u and hence a plane lying in Ω^4 . These two families of planes doubly rule Ω^4 . To a surface element or co-direction in P^3 , that is, a point x and incident plane u , is then associated all lines of P^3 lying in u and incident with x . In Ω^4 this corresponds to the intersection of the planes corresponding to x and u and is a line. Hence, the 5-dimensional spaces of co-directions in P^3 and lines in Ω^4 correspond naturally.

Note that the co-direction in P^3 consisting of the point $x_0 = {}^t(1, 0, 0, 0)$ and the incident plane $u_0: x_3 = 0$ in 3.2 corresponds to the line l_0 of Ω^4 joining the points ${}^t(0, 0, 0, 0, 1, 0)$ and ${}^t(0, 0, 0, 0, 0, 1)$ in 5.2. For, to the co-direction (x_0, u_0) is associated all lines of P^3 joining x_0 and a point $y = {}^t(y_0, y_1, y_2, 0)$ of u_0 ; such a line has Plücker coordinates

$$\begin{aligned} \xi_1 &= 0, & \xi_2 &= 0, & \xi_3 &= 0, \\ \xi_4 &= 0, & \xi_5 &= y_2, & \xi_6 &= y_1, \end{aligned}$$

and corresponds to a point of Ω^4 lying on l_0 .

The projectivity g in $PSL(4; \mathbf{C})$ permutes the lines of P^3 by $x \wedge y \rightarrow gx \wedge gy$, a projectivity of P^5 which preserves Ω^4 . In this way one obtains the isomorphism $A_3 \simeq D_3$:

$$PSL(4; \mathbf{C}) \simeq PSO(A; \mathbf{C}), \quad A = \begin{bmatrix} 0 & 1_3 \\ 1_3 & 0 \end{bmatrix},$$

[4, (25.8.4')]. The spaces of co-directions in P^3 and lines in Ω^4 are homogeneous under $PSL(4; \mathbf{C})$ and $PSO(A; \mathbf{C})$ respectively; hence the correspondence between these spaces is as homogeneous spaces. In fact, since (x_0, u_0) and l_0 correspond, their isotropy subgroups, as described in 3.2 and 5.2, correspond under the isomorphism.

From the isomorphism of the groups, we obtain the isomorphism of the Lie algebras $\mathfrak{sl}(4; \mathbf{C}) \simeq \mathfrak{o}(A; \mathbf{C})$, where X in $\mathfrak{sl}(4; \mathbf{C})$ is sent to the linear transformation $x \wedge y \rightarrow (Xx) \wedge y + x \wedge (Xy)$ in $\mathfrak{o}(A; \mathbf{C})$. With $X = (a_{ij})$, $i, j = 0, 1, 2, 3$, the matrix of this transformation with respect to the basis $e_i \wedge e_j$ is

$$\begin{bmatrix} a_{11} + a_{22} & -a_{23} & -a_{13} & 0 & a_{10} & -a_{20} \\ -a_{32} & a_{11} + a_{33} & -a_{12} & -a_{10} & 0 & a_{30} \\ -a_{31} & -a_{21} & a_{22} + a_{33} & a_{20} & -a_{30} & 0 \\ \hline 0 & -a_{01} & a_{02} & a_{00} + a_{33} & a_{32} & a_{31} \\ a_{01} & 0 & -a_{03} & a_{23} & a_{00} + a_{22} & a_{21} \\ -a_{02} & a_{03} & 0 & a_{13} & a_{12} & a_{00} + a_{11} \end{bmatrix};$$

Thus,

$$G = PSO(A; C), A = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 0 & 1_l \\ 0 & 1_l & 0 \end{bmatrix} \quad \text{or} \quad \begin{bmatrix} 0 & 1_l \\ 1_l & 0 \end{bmatrix}$$

and

$$G' = PSO(A'; C), A' = \begin{bmatrix} 2 \cdot 1_n & & & 0 \\ \hline & & & \\ & & -2 & 0 & 0 \\ & 0 & 0 & 0 & -1 \\ & & & 0 & -1 & 0 \end{bmatrix}.$$

These are groups of projectivities preserving Ω^{n+1} and Ψ^{n+1} , respectively, in P^{n+2} .

In case n is odd, the transformation which we consider is

$$\begin{aligned} \xi_1 &= \alpha_1 + \sqrt{-1} \alpha_2 & \xi_{l+1} &= \alpha_1 - \sqrt{-1} \alpha_2 \\ \xi_2 &= \alpha_3 + \sqrt{-1} \alpha_4 & \xi_{l+2} &= \alpha_3 - \sqrt{-1} \alpha_4 \\ & \vdots & & \vdots \\ \xi_{l-2} &= \alpha_{n-2} + \sqrt{-1} \alpha_{n-1} & \xi_{2l-2} &= \alpha_{n-2} - \sqrt{-1} \alpha_{n-1} \\ \xi_{l-1} &= \alpha_n + \lambda & \xi_{2l-1} &= \alpha_n - \lambda \\ \xi_l &= \mu & \xi_{2l} &= -v. \end{aligned}$$

This is a projectivity of P^{n+2} which sends the quadric Ψ^{n+1}

$$\alpha_1^2 + \dots + \alpha_n^2 - \lambda^2 - \mu v = 0$$

into the quadric Ω^{n+1}

$$2\xi_1\xi_{l+1} + \dots + 2\xi_l\xi_{2l} = 0.$$

In case n is even, the first equation of the transformation is $\xi_0 = \sqrt{2} \alpha_1$ and the remaining ones are like the above.

As before, we exhibit the details of the calculations for the case of n odd. For n even one need only carry along an additional initial row and column in the matrices; the conclusions are unchanged.

The matrix T of the transformation is

$$T = \begin{bmatrix} B & & & 0 & & \\ & 1 & 1 & 0 & 0 & \\ & 0 & 0 & 1 & 0 & \\ \bar{B} & & & 0 & & \\ & 1 & -1 & 0 & 0 & \\ 0 & & & & & \\ & 0 & 0 & 0 & -1 & \end{bmatrix},$$

where B is the $(l-2)$ by $(2l-4)$ matrix

$$B = \begin{bmatrix} 1 & \sqrt{-1} & & & & \\ & & 1 & \sqrt{-1} & 0 & \\ & & & & \cdot & \\ & 0 & & & \cdot & \\ & & & & \cdot & \\ & & & & & 1 & \sqrt{-1} \end{bmatrix}$$

and \bar{B} is its complex conjugate; T has inverse

$$T^{-1} = \frac{1}{2} \begin{bmatrix} {}^t\bar{B} & 0 & {}^tB & 0 & & \\ & 1 & 0 & 1 & 0 & \\ 0 & 0 & 1 & 0 & 0 & -1 & 0 \\ & 0 & 2 & 0 & 0 & 0 & \\ & 0 & 0 & 0 & 0 & -2 & \end{bmatrix}.$$

By direct calculation we ascertain the following:

- (1) $A' = {}^tTAT$ and hence $G' = T^{-1}GT$. G and G' are conjugate, but do not coincide, in $PSL(n+3; \mathbb{C})$. As a consequence, $g' = T^{-1}gT$.
- (2) $l'_0 = T^{-1}l_0$; the line l_0 in Ω^{n+1} joining

$${}^t(0, \dots, 0, 1, 0) \quad \text{and} \quad {}^t(0, \dots, 0, 0, 1)$$

is sent to the line l'_0 of Ψ^{n+1} joining

$${}^t(0, \dots, 0, 0 \mid 0, 0, 1) \quad \text{and} \quad {}^t(0, \dots, 0, 1 \mid -1, 0, 0).$$

Hence their isotropy subgroups, as in 5.2 and 4.3 are conjugate: $P' = T^{-1} P T$. As a consequence, $\mathfrak{p}' = T^{-1} \mathfrak{p} T$.

(3) The Cartan subalgebras of \mathfrak{g} and \mathfrak{g}' in 5.1 and 4.4 are conjugate: $\mathfrak{h}' = T^{-1} \mathfrak{h} T$. In fact, for

$$H = \text{diag}(h_1, \dots, h_l \mid -h_1, \dots, -h_l)$$

in \mathfrak{h} , we have

$$T^{-1} H T = \text{diag} \left[\begin{array}{cc} 0 & \sqrt{-1}h_1 \\ -\sqrt{-1}h_1 & 0 \end{array} \right], \dots, \left[\begin{array}{cc} 0 & \sqrt{-1}h_{l-2} \\ -\sqrt{-1}h_{l-2} & 0 \end{array} \right],$$

$$\left[\begin{array}{cccc} 0 & h_{l-1} & 0 & 0 \\ h_{l-1} & 0 & 0 & 0 \\ 0 & 0 & h_l & 0 \\ 0 & 0 & 0 & -h_l \end{array} \right]$$

in \mathfrak{h}' .

4) The elements W and W' of the Lie algebras which give the contact structures on G/P and G'/P' , as in 5.2 and 4.4, are conjugate: $W' = T^{-1} W T$. We conclude:

The $(2n-1)$ -dimensional manifolds of lines in Ω^{n+1} and lines in Ψ^{n+1} are isomorphic as algebraic homogeneous contact manifolds. The isomorphism is a consequence of the projectivity T carrying Ψ^{n+1} into Ω^{n+1} . T sends lines of Ψ^{n+1} into lines of Ω^{n+1} and is a contact transformation.

5.5. $G_0 = PSO(A; \mathbf{R})$ is a real form of G ; it consists of the elements of G fixed under the conjugation $g \rightarrow \bar{g}$ of G , complex conjugation of the matrix entries of g . The Cartan subalgebra \mathfrak{h} of \mathfrak{g} , as in 5.1, is stable and the maximal root $\rho = -\delta_{l-1} - \delta_l$ is real. With $P_0 = G_0 \cap P$, we obtain from 2.11 the real contact manifold

$$G_0/P_0 = \text{space of lines in } \Omega^{n+1} \text{ in real } P^{n+2},$$

a real form of G/P ; cf. 5.2. The same remarks apply to the real form $G'_0 = PSO(A'; \mathbf{R})$ of G' for the conjugation $g' \rightarrow \bar{g}'$. With $P'_0 = G'_0 \cap P'$, we obtain the real contact manifold

$$\begin{aligned} G'_0/P'_0 &= \text{space of lines in } \Psi^{n+1} \text{ in real } P^{n+2} \\ &= \text{space of pencils of mutually tangent oriented spheres in real } E^n \\ &= \text{space of oriented co-directions in real } E^n, \end{aligned}$$

a real form of G/P ; cf. 4.7.

Since $G' = T^{-1} G T$, we can exhibit G'_0/P'_0 , as well as G_0/P_0 , as a real form of the complex contact manifold G/P . $T G'_0 P^{-1}$ is the real form of $G = T G' T^{-1}$ consisting of the elements fixed under the conjugation obtained by transporting the conjugation $g' \rightarrow \bar{g}'$ of G' to G , namely

$$g \rightarrow T \overline{(T^{-1} g T)} T^{-1} = S^{-1} \bar{g} S$$

where $S = \bar{T} T^{-1}$. In the case of n odd,

$$S = \left[\begin{array}{cc|cc} 0 & 0 & 1_{l-2} & 0 \\ 0 & 1_2 & 0 & 0 \\ \hline 1_{l-2} & 0 & 0 & 0 \\ 0 & 0 & 0 & 1_2 \end{array} \right];$$

in the case of n even, S has an additional initial row and column with a 1 in their common first entry and 0s elsewhere. ${}^t S A S = A$ and $S^2 = 1_{n+3}$, so the complex conjugation $\xi \rightarrow S^{-1} \bar{\xi}$ preserves the quadric Ω^{n+1} . A point or line of Ω^{n+1} is fixed under this conjugation exactly if it is the image under T of a real point or line of Ψ^{n+1} . The latter constitute the orbit on Ω^{n+1} of $T G'_0 T^{-1}$. The isotropy subgroup in $T G'_0 T^{-1}$ of the line l_0 of Ω^{n+1} is $T G'_0 T^{-1} \cap P = T P'_0 T^{-1}$. Furthermore, the Cartan subalgebra \mathfrak{h} of \mathfrak{g} in 5.1 is stable under the conjugation $X \rightarrow S^{-1} \bar{X} S$ of \mathfrak{g} ; in fact, for

$$H = \text{diag} (h_1, \dots, h_l \mid -h_1, \dots, -h_l)$$

in \mathfrak{h} , we have

$$S^{-1} \bar{H} S = \text{diag} (-\bar{h}_1, \dots, -\bar{h}_{l-2}, \bar{h}_{l-1}, \bar{h}_l \mid \bar{h}_1, \dots, \bar{h}_{l-2}, -\bar{h}_{l-1}, -\bar{h}_l),$$

in case of n odd; the maximal root $\rho = -\delta_{l-1} - \delta_l$ is real, $\overline{\rho(S^{-1}\bar{H}S)} = \rho(H)$. Hence, the contact structure on TG'_0T^{-1}/TP'_0T^{-1} is that obtained from G/P by 2.11. We conclude:

G_0/P_0 and TG'_0T^{-1}/TP'_0T^{-1} , the latter isomorphic to G'_0/P'_0 , are two real forms of the complex contact manifold G/P .

5.6. We observed in 5.3 that the space of co-directions in complex projective space P^3 , by means of Plücker's line geometry, is isomorphic to the space of lines in the quadric Ω^4 in complex P^5 , and that this isomorphism makes real line geometry correspond to a real form of Ω^4 . We found in 5.4 and 5.5 that the space of oriented co-directions in complex Euclidean space E^3 of Lie's higher sphere geometry, which is the space of lines in the quadric Ψ^4 in complex P^5 , is isomorphic to the space of lines in the quadric Ω^4 also, and that this isomorphism makes real sphere geometry correspond to a second real form of Ω^4 . That is, real line geometry and real sphere geometry are two distinct real forms of complex line geometry. The line-sphere transformation establishes the isomorphism of the spaces of lines in Ψ^4 and lines in Ω^4 . The former places real sphere geometry in the foreground, the latter, real line geometry.

5.7. The isomorphism of 5.3 may be used to describe sphere geometry in terms of co-directions in complex P^3 . Real sphere geometry then leads to the real form $PSU(2,2)$ of $PSL(4; \mathbb{C})$.
