2. INDUCTION AND RECIPROCITY

The notion of induced representations for finite groups was introduced in 1898 by G. Frobenius in the paper [37]. In the same paper Frobenius established what is now called the Frobenius reciprocity relation. We recall his basic construction which is fundamental in the entire theory of group representations.¹⁾

Let G be a finite group and let P be a subgroup of G . Let π be a representation of G on a finite dimensional vector space V . That is $\pi: G \rightarrow GL(V)$ is a homomorphism of G into the group of non-singular endomorphisms of V . We shall also refer to V as a (left) G module. By restriction V is also a P module. Conversely there is a functor I which converts P modules to G modules: Given a P module W the G module IW is defined to be the space of functions $f: G \rightarrow W$ such that $f(ap) = p^{-1} \cdot f(a)$ for every (a, p) in $G \times P$. The action of G on IW is defined by

$$(a \cdot f)(x) = f(a^{-1}x)$$

for (f, a, x) in $(IW) \times G \times G$. IW is called the G module *induced* by the P module W . Induction and restriction are related in the following way.

THEOREM 2.1 (Frobenius reciprocity relation, 1898). *If W is a P module and if V is a G module then*

$$\text{Hom}_G(V, IW) = \text{Hom}_P(V, W).$$

We wish to consider extensions or analogues of this relation in a wider context. For this it is most convenient first of all to re-describe the G module IW . The following "geometric" interpretation of IW is well-known. Consider the right action of P on $G \times W$ given by

$$(a, w) \cdot p = (ap, p^{-1}w)$$

for (a, p, w) in $G \times P \times W$. Let

$$(2.2) \quad E_W = \text{orbit space } (G \times W)/P = G \times_P W.$$

Let $\gamma: E_W \rightarrow G/P$ be the canonical (well-defined) map $[a, w] \rightarrow aP$, where $[a, w]$ is the orbit of $(a, w) \in G \times W$. For each $a \in G$ the map $w \rightarrow [a, w]$ of W to $\gamma^{-1}\{aP\}$ is a bijection. That is we may identify W as the fibre over each point of

¹⁾ For the theory of induced representations of locally compact groups see G. Mackey [55], [56].

G/P . G acts naturally on E_W and G/P on the left. γ is an equivariant map. Let $\Gamma(E_W)$ be the space of sections of E_W . That is $s \in \Gamma(E_W)$ is a map from G/P to E_W satisfying $\gamma \circ s = 1$; hence s maps each point to the fibre over it. $\Gamma(E_W)$ is a left G module:

$$(2.3) \quad (a \cdot s)(x) = a \cdot s(a^{-1} \cdot x)$$

for (a, s, x) in $G \times \Gamma(E_W) \times G/P$. Moreover

PROPOSITION 2.4. *There is a natural G module isomorphism $s \rightarrow f^s$ of $\Gamma(E_W)$ onto IW such that for every a in G , $s(aP) = [a, f^s(a)]$. Hence by Theorem 2.1*

$$(2.5) \quad \text{Hom}_G(V, \Gamma(E_W)) = \text{Hom}_P(V, W).$$

This sets the stage for a possible extension of Frobenius. Namely, following Bott, we consider the following data. G is a complex Lie group, P is a closed complex Lie subgroup (thus the injection $P \rightarrow G$ is holomorphic), and W is a finite dimensional holomorphic P module (i.e. for each w in W and f in the complex dual space of W the map $p \rightarrow f(p \cdot w)$ of P to the complex numbers is holomorphic). We define E_W exactly as above. Then E_W has the structure of a holomorphic vector bundle over the complex manifold G/P . Let $\Gamma(E_W)$ now denote the space of C^∞ sections with the G module structure given by (2.3) and let $\Gamma_{\text{hol}}(E_W)$ denote the G stable subspace of holomorphic sections. Since all of our data is now holomorphic the most natural question to ask, considering (2.5), is: When is it true that

$$(2.6) \quad \text{Hom}_G(V, \Gamma_{\text{hol}}(E_W)) = \text{Hom}_P(V, W)$$

for a holomorphic G module V ? (2.6) would then represent an exact holomorphic analogue of Frobenius reciprocity. It turns out that (2.6) is valid if the space G/P is sufficiently nice. For example suppose that G/P is a compact simply connected Kahler manifold. Group theoretically this means that G is a connected complex semisimple Lie group and P is a parabolic subgroup. Then it is due to Bott [12] that (2.6) is valid. In fact in [12] Bott proves considerably more: Let SE_W be the sheaf of germs of local holomorphic sections of E_W and let $H^*(G/P, SE_W)$ be the cohomology of G/P with coefficients in SE_W . Then we have

THEOREM 2.7 (R. Bott, 1957). *Suppose G is a connected complex semisimple Lie group and P is a parabolic subgroup of G . Let \mathfrak{p} be the Lie algebra of P and let V, W be finite dimensional holomorphic G and P modules respectively. Then*

$$(2.8) \quad \text{Hom}_G(V, H^j(G/P, SE_W)) = H^j(p, p \cap \bar{p}, \text{Hom}(V, W))$$

for each $j \geq 0$.

The bar $\bar{}$ denotes conjugation of G with respect to a maximal compact subgroup K of G and the right hand side of (2.8) is the *relative* Lie algebra cohomology of p (in the sense of Hochschild, Serre [44]). Here $H^j(G/P, SE_W)$ ¹ has the G module structure induced by the left action of G on E_W and $\text{Hom}(V, W)$ has the p module structure defined by

$$(2.9) \quad (x \cdot \phi)(v) = -\phi(x \cdot v) + x \cdot \phi(v)$$

for (x, ϕ, v) in $p \times \text{Hom}(V, W) \times V$.

Remarks. (i) For $j = 0$, $H^0(p, p \cap \bar{p}, \text{Hom}(V, W))$ is independent of the subalgebra $p \cap \bar{p}$ of p and has the value $\text{Hom}(V, W)^P$ (the space of invariants) which is precisely $\text{Hom}_p(V, W) = \text{Hom}_P(V, W)$ by (2.9) (P is connected). Also $H^0(G/P, SE_W)$ is precisely $\Gamma_{\text{hol}}(E_W)$. Thus taking $j = 0$ in (2.8) we get

$$\text{Hom}_G(V, \Gamma_{\text{hol}}(E_W)) = \text{Hom}_P(V, W)$$

which is (2.6). This shows that (2.8) represents a rather remarkable extension of Frobenius reciprocity to higher cohomology. Here the induction functor is $I: W \rightarrow H^*(G/P, SE_W)$.

(ii) As shown by Bott (2.8) is valid, more generally, for C -spaces G/P in the sense of Wang [90]. The latter need not be Kahler, as we have assumed for our purposes.

The functor I in remark (i) can be explicated by the use of differential forms: Let $\Lambda^{0,j}(G/P, E_W)$ denote the space of E_W valued C^∞ differential forms on G/P of pure type $(0, j)$. That is

$$\omega \in \Lambda^{0,j}(G/P, E_W)$$

assigns to each $x \in G/P$ a skew-symmetric j linear map

$$\omega_x: T_x(G/P)^{\mathbb{C}} \times \dots \times T_x(G/P)^{\mathbb{C}} \rightarrow (E_W)_x = \gamma^{-1}\{x\}$$

on the complexified tangent space $T_x(G/P)^{\mathbb{C}}$ of G/P at x to the fiber $(E_W)_x$ over x such that (a) given smooth vector fields X_1, \dots, X_j on G/P the map

$$\omega(X_1, \dots, X_j): x \rightarrow \omega_x(X_{1x}, \dots, X_{jx})$$

is C^∞ —i.e. it belongs to $\Gamma(E_W)$ and (b) for each real number θ ,

$$\omega(U_\theta X_1, \dots, U_\theta X_j) = e^{-\sqrt{-1}j\theta} \omega(X_1, \dots, X_j)$$

¹) Since G/P is compact $H^j(G/P, SE_W)$ is known to be finite-dimensional.

where

$$U_\theta X_l = \cos \theta X_l + \sin \theta JX_l$$

and J is the complex structure tensor on G/P . Let $\bar{\partial}: \Lambda^{0,j} \rightarrow \Lambda^{0,j+1}$ denote, as usual, the Cauchy-Riemann operator so that $\bar{\partial}^2 = 0$. If f is a C^∞ function on G/P and X is a C^∞ vector field on G/P then

$$(2.10) \quad (\bar{\partial}f)(X) = \frac{1}{2} [Xf + \sqrt{-1} (JX)f].$$

Since $\bar{\partial}^2 = 0$ let $H_{\bar{\partial}}^{0,j}(G/P, E_W)$ denote the corresponding $\bar{\partial}$ cohomology:

$$(2.11) \quad \begin{aligned} & H_{\bar{\partial}}^{0,j}(G/P, E_W) \\ &= \frac{\ker \bar{\partial}: \Lambda^{0,j}(G/P, E_W) \rightarrow \Lambda^{0,j+1}(G/P, E_W)}{\bar{\partial}\Lambda^{0,j-1}(G/P, E_W)}. \end{aligned}$$

By Dolbeault's theorem [35]

$$(2.12) \quad H^j(G/P, SE_W) = H_{\bar{\partial}}^{0,j}(G/P, E_W).$$

The induced action of G on $H_{\bar{\partial}}^{0,j}(G/P, E_W)$ is given explicitly as follows. First G acts on $\Lambda^{0,j}(G/P, E_W)$ by

$$(2.13) \quad \begin{aligned} & (a \cdot \omega)_x(L_1, \dots, L_j) \\ &= a \cdot \omega_{a^{-1}x}(dl_{a^{-1}x}(L_1), \dots, dl_{a^{-1}x}(L_j)) \end{aligned}$$

where

$$(a, \omega, x) \in G \times \Lambda^{0,j}(G/P, E_W) \times G/P,$$

each $L_i \in T_x(G/P)^{\mathbb{C}}$ and dl_{a_x} is the derivative of left translation $l_a: G/P \rightarrow G/P$ on G/P at x . Note that (2.13) generalizes the action of G on

$$\Gamma(E_W) = \Lambda^{0,0}(G/P, E_W)$$

given in (2.3). Because left translation is holomorphic the diagram

$$\begin{array}{ccc} \Lambda^{0,j}(G/P, E_W) & \xrightarrow{\bar{\partial}} & \Lambda^{0,j+1}(G/P, E_W) \\ a \downarrow & & \downarrow a \\ \Lambda^{0,j}(G/P, E_W) & \xrightarrow{\bar{\partial}} & \Lambda^{0,j+1}(G/P, E_W) \end{array}$$

is commutative for each a in G . Thus (2.13) induces a well-defined action of G on $H_{\bar{\partial}}^{0,j}(G/P, E_W)$. We may now write (2.8) as

$$(2.14) \quad \text{Hom}_G(V, H_{\bar{\partial}}^{0,j}(G/P, E_W)) = H^j(p, p \cap \bar{p}, \text{Hom}(V, W)).$$

Now assume that W is in fact irreducible. The parabolic subalgebra p has a decomposition $p = (p \cap \bar{p}) \oplus n$ into a reductive part $p \cap \bar{p}$ and a nilpotent part $n =$ an ideal in p . By general principles

$$\begin{aligned} H^j(p, p \cap \bar{p}, \operatorname{Hom}(V, W)) &= H^j(n, \operatorname{Hom}(V, W))^{p \cap \bar{p}} \\ &= H^j(n, V^* \otimes W)^{p \cap \bar{p}} = (H^j(n, V^*) \otimes W)^{p \cap \bar{p}}. \end{aligned}$$

The last statement of equality follows by the irreducibility of W since by Lie's theorem, W is a trivial n module. Now

$$(H^j(n, V^*) \otimes W)^{p \cap \bar{p}} = \operatorname{Hom}_{p \cap \bar{p}}(W^*, H^j(n, V^*)).$$

From (2.14) we obtain (see [50]).

THEOREM 2.15 (Bott-Kostant reciprocity, 1960). *Let G, P be as in Theorem 2.7, let n be the nilradical of the parabolic subalgebra p , and let W be a finite dimensional irreducible holomorphic P module. Then for any finite dimensional holomorphic G module V we have*

$$(2.16) \quad \operatorname{Hom}_G(V, H_{\bar{\partial}}^{0,j}(G/P, E_W)) = \operatorname{Hom}_{p \cap \bar{p}}(W^*, H^j(n, V^*)).$$

Again $p \cap \bar{p}$ is the reductive part of p where the bar denotes conjugation of $G = K^{\mathbb{C}}$ with respect to a maximal compact subgroup K . We refer to (2.16) as "the debut of n cohomology"! Since 1960 it has played some rather important roles in both finite dimensional and infinite dimensional representation theory. There is an equivalent version of (2.16): The G module structure on $H_{\bar{\partial}}^{0,j}(G/P, E_W)$ induced by (2.13) may be restricted to K . Let \hat{K} denote, as usual, the equivalence classes of the irreducible unitary representations of K and let V_{π} be the representation space of $\pi \in \hat{K}$. Then we have (again for W irreducible).

THEOREM 2.17 (B. Kostant). *The decomposition of $H_{\bar{\partial}}^{0,j}(G/P, E_W)$ as a K module is*

$$\begin{aligned} (2.18) \quad H_{\bar{\partial}}^{0,j}(G/P, E_W) &= \sum_{\pi \in \hat{K}} V_{\pi} \otimes \operatorname{Hom}_{p \cap \bar{p}}(W^*, H^j(n, V_{\pi}^*)) \\ &= \sum_{\pi \in \hat{K}} V_{\pi}^* \otimes \operatorname{Hom}_{p \cap \bar{p}}(W^*, H^j(n, V_{\pi})). \end{aligned}$$

In the direct sum on the right hand side the action of K on a summand is $\pi \otimes 1$ or $\pi^* \otimes 1$ in the second equation.

From (2.18) (or from (2.16)) we see that the multiplicity of an irreducible K module V_{π} in $H_{\bar{\partial}}^{0,j}(G/P, E_W)$ is governed precisely by the n cohomology

$H^j(n, V_\pi^*)$. Here, by analytic continuation, we consider V_π also as a representation of the complex Lie algebra of G . Its n module structure is the restriction thereof to n .

Remarks. (i) In contrast to remark (ii) made earlier, following Theorem 2.7, Theorems (2.15) and (2.17) do require that G/P should be Kahler.

(ii) One knows that K acts transitively on G/P so that G/P is diffeomorphic to $K/K \cap P$.

Now Kostant in [50] has computed the Lie algebra cohomology groups $H^j(n, V_\pi^*)$. Two outstanding consequences of his results, among others, which we shall briefly discuss are (a) Weyl's character formula and (b) Bott's generalized Borel-Weil theorem. Suppose more generally that g is any complex semisimple Lie algebra (for example g could be the Lie algebra of G above). Let $h \subset g$ be a Cartan subalgebra of g , let Δ be the set of non-zero roots of (g, h) , and let Δ^+ be a choice of positive roots. The equivalence classes of finite dimensional irreducible representations of g (over the complex numbers) correspond univalently to linear functionals Λ on h which satisfy the condition that $2 \frac{(\Lambda, \alpha)}{(\alpha, \alpha)}$ is a non-negative integer for each α in Δ^+ . That is Λ is Δ^+ dominant integral; $(,)$ denotes the Killing form on g . This is Cartan's highest weight theory alluded to in the introduction. Let π_Λ be a finite dimensional irreducible representation of g with corresponding highest weight $\Lambda \in h^*$. Its character $X_\Lambda: h \rightarrow \mathbb{C}$ is defined to be the function $H \rightarrow \text{trace exp } \pi_\Lambda(H)$, $H \in h$. This definition is independent of the choice of Cartan subalgebra h since any two are conjugate. We consider the special "minimal" parabolic subalgebra $p \subset g$ whose nilradical is

$$(2.19) \quad n = \sum_{\alpha \in \Delta^+} g_\alpha$$

and whose reductive part is h where g_α is the root space of $\alpha \in \Delta$. That is p is just the Borel subalgebra $h + n$. Let V_Λ denote the representation space of π_Λ . Then by restriction to n we again form the Lie algebra cohomology groups $H^j(n, V_\Lambda)$. Let θ denote the adjoint representation of h on Λn^* . Then $\theta \otimes \pi_\Lambda$ defines a representation of h on the cochain complex $\Lambda n^* \otimes V_\Lambda$. This h action commutes with the coboundary operator and therefore passes to cohomology. Applying the Euler-Poincaré principle one gets

$$(2.20) \quad \left. \sum_{j=0}^{\dim n} (-1)^j \text{trace exp } \theta \otimes \pi_\Lambda(H) \right|_{\Lambda n^* \otimes V_\Lambda} = \left. \sum_{j=0}^{\dim n} (-1)^j \text{trace exp } \theta \otimes \pi_\Lambda(H) \right|_{H^j(n, V_\Lambda)}$$

for each H in h . One evaluates the left hand side of (2.20) by general principles and the right hand side using Kostant's main theorem, Theorem 5.14 of [50]. Actually Theorem 5.14 of [50] gives the h_1 module structure of $H^j(n_1, V_\Lambda)$ for an arbitrary parabolic $p_1 = h_1 + n_1$ of g with reductive and nilpotent parts h_1, n_1 respectively. For the derivation of Weyl's formula only the simplest case $p_1 = p = h + n$ is needed, where n is given in (2.19). Thus we shall state only a special case of Kostant's result.

THEOREM 2.21 (B. Kostant, 1960). *The decomposition of $H^j(n, V_\Lambda)$ as a h module is*

$$H^j(n, V_\Lambda) = \sum_{\sigma \in \text{Weyl group } \mathcal{W} \text{ of } (g, h) \text{ such that } l(\sigma) = j} V_{\Lambda, \sigma},$$

where each summand $V_{\Lambda, \sigma}$ in the direct sum is one-dimensional and $H \in h$ acts on $V_{\Lambda, \sigma}$ by the scalar $[\sigma(\Lambda + \delta) - \delta](H)$.

Here by definition $2\delta = \sum_{\alpha \in \Delta^+} \alpha$ and $l(\sigma)$ (the length of σ) is the cardinality of the set $\Delta^+ \cap \sigma(-\Delta^+)$. From the remarks following (2.20) and the knowledge of n cohomology given by Theorem 2.21 one derives Weyl's famous character formula [93]:

THEOREM 2.22 (H. Weyl, 1926). *For $H \in h$*

$$X_\Lambda(H) = \frac{\sum_{\sigma \in \mathcal{W}} (\det \sigma) e^{[\sigma(\Lambda + \delta)](H)}}{\prod_{\alpha \in \Delta^+} (e^{\alpha(H)/2} - e^{-\alpha(H)/2})}.$$

The denominator is also given by the sum $\sum_{\sigma \in \mathcal{W}} (\det \sigma) e^{(\sigma\delta)(H)}$ (this fact can be proved too using n cohomology) and $\det \sigma = (-1)^{l(\sigma)}$. As a corollary of Theorem 2.22 one obtains Weyl's formula for the dimension of the irreducible module V_Λ in terms of its highest weight Λ . The result is

$$(2.23) \quad \dim V_\Lambda = \frac{\prod_{\alpha \in \Delta^+} (\Lambda + \delta, \alpha)}{\prod_{\alpha \in \Delta^+} (\delta, \alpha)}.$$

Kostant's result on n cohomology can also be used to derive the generalized Borel-Weil theorem. Here one may apply formula (2.18) decisively. Let g now denote the Lie algebra of G . Extend a maximal abelian subalgebra of the Lie algebra of K to a Cartan subalgebra h of g . Again let $\Delta^+ \subset \Delta$ be a choice of positive roots where Δ is the set of non-zero roots of (g, h) and let $2\delta = \sum_{\alpha \in \Delta^+} \alpha$.

We choose the parabolic P such that its Lie algebra p contains the Borel subalgebra $h + \sum_{\alpha \in \Delta^+} g_{-\alpha}$. h is also a Cartan subalgebra of the reductive Lie algebra $p \cap \bar{p}$ so that we have the decompositions

$$(2.24) \quad p = (p \cap \bar{p}) \oplus n, \quad p \cap \bar{p} = h + \sum_{\alpha \in \Delta(p \cap \bar{p})} g_{\alpha}$$

$$n = \sum_{\alpha \in \Delta^+ - \Delta(p \cap \bar{p})} g_{-\alpha}$$

where $\Delta(p \cap \bar{p})$ is the set of roots of $(p \cap \bar{p}, h)$.

Let W be an irreducible holomorphic P module. Then W is an irreducible $p \cap \bar{p}$ module thereby such that $n \cdot W = 0$. We let Λ denote its highest weight relative to the positive system $\Delta^+ \cap \Delta(p \cap \bar{p})$ for $p \cap \bar{p}$. Applying Kostant's n cohomology theorem to (2.18) one obtains (see [12], [50]).

THEOREM 2.25 (R. Bott, 1957). *The spaces $H_{\bar{\partial}}^{0,j}(G/P, E_W)$ vanish for all but at most one j . If*

$$H_{\bar{\partial}}^{0,j_0}(G/P, E_W) \neq 0$$

then $H_{\bar{\partial}}^{0,j_0}(G/P, E_W)$ is an irreducible K module.

More precisely we have the following. Let Λ be the highest weight of W (as above) relative to the positive roots in the reductive part of P . If $(\Lambda + \delta, \alpha) = 0$ for some α in Δ then $H_{\bar{\partial}}^{0,j}(G/P, E_W) = 0$ for every j . If $(\Lambda + \delta, \alpha) \neq 0$ for each α in Δ (i.e. $\Lambda + \delta$ is *regular*) there is a unique element σ in the Weyl group of (g, h) such that $(\sigma(\Lambda + \delta), \alpha) > 0$ for every $\alpha \in \Delta^+$. Then $H_{\bar{\partial}}^{0,j}(G/P, E_W) = 0$ for $j \neq l(\sigma)$ where again $l(\sigma)$ is the length of σ (see remarks following Theorem 2.21). Moreover $H_{\bar{\partial}}^{0,l(\sigma)}(G/P, E_W)$ is an irreducible K module (= an irreducible g module since g is the complexification of the Lie algebra of K) with highest weight $\sigma(\Lambda + \delta) - \delta$ relative to Δ^+ .

Remarks. (i) By definition of σ it follows that

$$\sigma^{-1}\Delta^- \cap \Delta^+ = \{\alpha \in \Delta^+ \mid (\Lambda + \delta, \alpha) < 0\}.$$

Also since Λ is a highest weight $(\Lambda, \alpha) \geq 0$ for

$$\alpha \in \Delta^+ \cap \Delta(p \cap \bar{p}) \Rightarrow (\Lambda + \delta, \alpha) > 0$$

for

$$\alpha \in \Delta^+ \cap \Delta(p \cap \bar{p}).$$

Hence

$$\begin{aligned} & \{\alpha \in \Delta^+ \mid (\Lambda + \delta, \alpha) < 0\} \\ &= \{\alpha \in \Delta^+ - (\Delta^+ \cap \Delta(p \cap \bar{p})) \mid (\Lambda + \delta, \alpha) < 0\} \end{aligned}$$

so that $l(\sigma)$ in Theorem 2.25 has the value

$$|\{\alpha \in \Delta^+ - (\Delta^+ \cap \Delta(p \cap \bar{p})) \mid (\Lambda + \delta, \alpha) < 0\}|^1).$$

$$\Delta^+ - \Delta^+ \cap \Delta(p \cap \bar{p})$$

is the set of roots in the nilradical of the "opposite" parabolic \bar{p} . Since

$$(\sigma(\Lambda + \delta), \sigma\alpha) = (\Lambda + \delta, \alpha) > 0$$

for $\alpha \in \Delta^+ \cap \Delta(p \cap \bar{p})$ (as we have just seen) we also conclude that the Weyl group element σ in Theorem 2.25 satisfies

$$\Delta^- \cap \Delta(p \cap \bar{p}) \subset \sigma^{-1} \Delta^-.$$

(ii) The irreducible holomorphic P modules W in the statement of Theorem 2.25 can be obtained as follows. Start with an arbitrary irreducible representation π of $P \cap K$ on a complex vector space W . Since $p \cap \bar{p}$ is the complexification of the Lie algebra of $P \cap K$, π defines a unique irreducible representation π on p such that $\pi(n) = 0$. This infinitesimal representation can be "integrated" to a representation of P since P and $P \cap K$ have the same fundamental groups. Thus every irreducible representation π of $P \cap K$ extends uniquely to an irreducible holomorphic representation of P . The highest weight Λ of π is integral and $\Delta^+ \cap \Delta(p \cap \bar{p})$ dominant. Conversely if G is simply connected, any integral $\Lambda \in h^*$ which is $\Delta^+ \cap \Delta(p \cap \bar{p})$ dominant is the highest weight of irreducible representation of $P \cap K$ and hence is the highest weight of an irreducible holomorphic representation of P .

(iii) Suppose in particular G is simply connected, p is chosen to be

$$h + \sum_{\alpha \in \Delta^+} g_{-\alpha},$$

and that Λ is Δ^+ dominant integral. Then in Theorem 2.25 $\sigma = 1$ so that the irreducible K, G or g module with highest weight Λ is given by $H_{\theta}^{0,0}(G/P, E_W) = \text{space of holomorphic sections of the line bundle } E_W$. Indeed $\dim_{\mathbb{C}} W = 1$ since in this case $P \cap K$ is abelian. This gives the geometric realization of V_{Λ} [11].

¹⁾ $|S|$ denotes the cardinality of a set S .
