TREES, TAIL WAGGING AND GROUP PRESENTATIONS

by M. A. Armstrong

The Bass-Serre theorem gives a presentation for a group of automorphisms of a tree. Like all good theorems it has attracted considerable attention and there are now several proofs available [4], [3], [1]. Our goal is a natural elementary proof which makes maximal use of the geometry of the tree.

1. Graphs

A graph X consists of two sets E (directed edges) and V (vertices) and two functions

$$E \to E, \quad e \mapsto \overline{e}$$

 $E \to V \times V, \quad e \mapsto (i(e), t(e))$

which satisfy $\overline{e} = e$, $\overline{e} \neq e$ and $i(\overline{e}) = t(e)$ for each $e \in E$. The vertices i(e), t(e) are the initial and terminal vertices of the directed edge e, and \overline{e} is the reverse of e. Henceforth we refer to directed edges simply as edges.

A path in X joining vertex u to vertex v is an ordered string of edges $e_1e_2 \dots e_n$ such that $i(e_1) = u$, $i(e_{k+1}) = t(e_k)$ for $1 \le k \le n-1$, and $t(e_n) = v$. If v = u we have a circuit. A path of the form $e\bar{e}$ is a round trip and a circuit which does not contain any round trips will be called a loop. If any two distinct vertices may be joined by a path then the graph is connected. A tree is a connected graph which does not contain any loops.

Let X be a tree. A path in X is a geodesic if it does not contain any round trips. Given distinct vertices u, v of X there is a unique geodesic \overrightarrow{uv} which joins u to v.

An action of a group G on a graph X is an action of G on E and on V such that $g\overline{e} = \overline{ge}$, i(ge) = gi(e), t(ge) = gt(e) and $ge \neq \overline{e}$ for each $e \in E$. Because group elements are not allowed to reverse edges we have a quotient graph X/G. When G acts on X we shall often say that G is a group of automorphisms of X.

We adopt the usual notation whereby G_x denotes the stabilizer of a vertex x. If $g \in G$ happens to fix x we write g_x for the element g thought of as a member of G_x . Of course G_e denotes the stabilizer of the edge e. If x is a vertex of e then G_e is a subgroup of G_x .

Suppose G acts on a tree X. If $g \in G$ fixes the vertices u, v then it must fix the whole geodesic \overrightarrow{uv} , since otherwise the image of \overrightarrow{uv} under g would be a second geodesic from u to v.

2. LIFTING EDGES

Let G be a group of automorphisms of a tree X. Choose a maximal tree M in X/G and lift it [4, Proposition I.14] to a subtree T of X. The vertices of T form a set of representatives for the action of G on the vertices of X. For each pair of edges f, \bar{f} from X/G - M select one, say f, and lift it to an edge e of X which has its initial vertex x in T. Exactly one vertex z of T lies in the same orbit as t(e) and we choose an element γ_f from G that maps z onto t(e). We can now lift \bar{f} to $(\gamma_f)^{-1}\bar{e}$. This has its initial vertex z in T and $\gamma_{\bar{f}} = (\gamma_f)^{-1}$ sends the vertex x of T to its terminal vertex (Figure 1). Finally we extend the correspondence $f \to \gamma_f$ over the edges of M by setting $\gamma_f = 1$ (the identity element of G) whenever $f \in M$.

The Bass-Serre theorem [4, Theorem I.13] gives the following presentation for G.

- (a) Generators. The elements of all the G_w where w is a vertex of T and the γ_f where f is an edge of X/G.
- (b) Relations. The internal relations of each stabilizer G_w together with $\gamma_f = 1$ if f is an edge of M, $\gamma_{\bar{f}} = (\gamma_f)^{-1}$ and

 $\gamma_{\bar{f}} g_x \gamma_f = (\gamma_{\bar{f}} g \gamma_f)_z$ where *e* is the chosen lift of *f* and $g \in G_e$. (If *f* is an edge of *M* then z = t(e) and the final relation reduces to $g_x = g_z$ whenever $g \in G_e$).
