 $<\frac{2a_{n_0-1}}{a_{n_0}}$  . Then, appealing to (5.20), we obtain

$$1 < \phi_1 \dots \phi_{n_0} < \frac{2a_0}{a_{n_0}B_{n_0-3}}$$
,

so that, by (5.17), we have

$$\frac{a_{n_0}}{a_0} < \delta < \frac{2}{B_{n_0-3}} .$$

It remains to consider the case  $n_0 = 1$ . If  $I_0$  is reduced then  $\delta = 1$ . If  $I_0$  is not reduced then  $\delta = \frac{a_1}{a_0} \phi_1$  and, as above, we have  $1 < \phi_1 < \frac{2a_0}{a_1}$ , giving  $\frac{a_1}{a_0} < \delta < 2$ .

Hence in all cases we have  $\frac{1}{a_0} \le \delta < 2$ . All subsequent Lagrange neighbours of I are reduced by Lemma 5. This completes the proof of Proposition 7.

## 6. Periods of reduced cycles

We show that any two equivalent reduced, primitive ideals of the same order  $O_D$  can be obtained from one another by using the Lagrange reduction process described in §5.

PROPOSITION 8. ([5]: §31, [12]: Theorem 4.5) Let  $I = a[1, \phi] \ (a > 0)$  and  $J = b[1, \psi] \ (b > 0)$  be two equivalent, reduced, primitive ideals of  $O_D$ , so that  $[1, \psi] = \rho[1, \phi]$  for some  $\rho(> 0) \in K^*$ . Interchanging I and J if necessary we may suppose that  $\rho \geqslant 1$ . Set  $I_0 = I$ . Then there exists a non negative integer n such that  $J = I_n$  and  $\rho = \phi_1 \dots \phi_n$ , so that  $J = I_n = \rho_n I$ .

*Proof.* Recalling that  $\phi_n > 1 (n \ge 1)$ , we see from (5.10) and (5.13) that the sequence  $\{\phi_1 \dots \phi_n\}_{n=0}^{\infty}$  is monotonically increasing and unbounded. Hence there exists an integer  $n \ge 0$  such that  $\phi_1 \dots \phi_n \le \rho < \phi_1 \dots \phi_{n+1}$ . As  $I_n = \frac{a_n}{a_0} \phi_1 \dots \phi_n I_0$  (by (5.5)), we have  $\frac{1}{b} J = \frac{\rho}{\phi_1 \dots \phi_n} \frac{1}{a_n} I_n$ . If  $\rho = \phi_1 \dots \phi_n$  then

 $\frac{1}{b}J = \frac{1}{a_n}I_n$  and so, by Proposition 2 (iii), we have  $b = a_n$  and  $J = I_n$  as required. This we may suppose that  $\rho > \phi_1 \dots \phi_n$ . Replacing  $I_0$  by  $I_n$ , we obtain

(6.1) 
$$\frac{1}{b}J = \rho \frac{1}{a_0}I_0$$
, where  $1 < \rho < \phi_1$ .

From (6.1), we see that  $\frac{a_0}{\rho}J = bI_0$ , and so, as  $J\bar{J} = (b)$ , we have  $\frac{a_0}{\rho} = I_0\bar{J}$ ,

showing that  $\frac{1}{\rho} \in \frac{1}{a_0} I_0$ . Next we observe that

$$\frac{1}{a_0}I_0=\frac{1}{\phi_1a_1}I_1=\frac{1}{\phi_1}[1,\phi_1]=\left[1,\frac{1}{\phi_1}\right],$$

so there are integers x and y such that

$$\frac{1}{\rho} = x + \frac{y}{\Phi_1}.$$

Thus, as  $1 < \rho < \phi_1$ , we have

$$\frac{1}{\phi_1} < x + \frac{y}{\phi_1} < 1 \ .$$

Appealing to (6.1), we obtain

$$J = \frac{b\rho}{a_0} I_0 = \frac{b\rho}{a_1 \phi_1} I_1 = \frac{b\rho}{\phi_1} [1, \phi_1],$$

so that  $\frac{b\rho}{\phi_1} \in J$ , and  $0 < \frac{b\rho}{\phi_1} < b$ . As J is reduced, by Proposition 4, we have

$$\left| \frac{b\rho}{\bar{\phi}_1} \right| = \frac{b|\rho|}{|\bar{\phi}_1|} > b$$
, so that  $\left| \frac{1}{\bar{\rho}} \right| < \left| \frac{1}{\bar{\phi}_1} \right|$ , that is

$$\left| x + \frac{y}{\bar{\varphi}_1} \right| < \frac{1}{|\bar{\varphi}_1|}.$$

From (6.2) we see that  $y \neq 0$ . Then (6.3) shows that  $x \neq 0$ , and that, as  $\bar{\phi}_1 < 0$ , xy > 0. This contradicts (6.2), and completes the proof of Proposition 8.

Let  $I_0$  be a reduced, primitive ideal of a class C of  $O_D$ . By the Lagrange reduction process described in §5, we obtain (by Proposition 5) an infinite

sequence  $\{I_n\}_{n=0}^{\infty}$  of reduced, primitive ideals with each ideal  $I_n$  equivalent to  $I_0$ . By Proposition 8, this sequence contains all the reduced, primitive ideals of the class C. As C contains only a finite number of reduced, primitive ideals (§4), there exist integers r and l with  $0 \le r < r + l$  such that  $I_r = I_{r+l}$ . Applying Proposition 6 (ii), we obtain successively  $I_{r-1} = I_{r+l-1}, I_{r-2} = I_{r+l-2}, \ldots$ , and, after r steps, we have  $I_0 = I_l$ , which shows that the sequence  $\{I_n\}_{n=0}^{\infty}$  is purely periodic.

Definition 12. (Period) Let  $I_0$  be a reduced, primitive ideal of a class C of  $O_D$ . Let I be the least positive integer with  $I_0 = I_l$ . The set  $\{I_0, ..., I_{l-1}\}$  is called the *period* of the class C. The length of the period is the integer I.

The period of the class C of  $O_D$  consists of all the reduced, primitive ideals in C. It is easy to see that if  $I_s = I_t$  then l divides s - t. As  $I_l = I_0$ , we see, from (5.5), that  $I_0 = \eta I_0$ , where

$$\eta = \rho_l = \prod_{i=1}^l \phi_i,$$

and so, by Proposition 2 (ii),  $\eta$  is a unit (> 1) of  $O_D$ .

PROPOSITION 9. (i) If  $I = I_0$  and J are equivalent, reduced, primitive ideals of  $O_D$  with  $J = \alpha I_0$ , where  $\alpha (\geqslant 1) \in K^*$ , then there exist unique integers q and s such that

$$\alpha = \eta^q \rho_s$$
 ( $\rho_s$  is defined in (5.5),  $\eta$  in (6.4))

where

$$q \geqslant 0$$
,  $0 \leqslant s \leqslant l - 1$ .

(ii) If J = I then we have s = 0 and  $\alpha = \eta^q$ .

*Proof.* (i) By Proposition 8 there exists a nonnegative integer n such that

$$J = I_n = \rho_n I_0$$
,  $\alpha = \rho_n$ .

Let  $q \ge 0$  and s be the integers defined uniquely by

$$n = ql + s$$
,  $0 \le s \le l - 1$ .

Then, by periodicity, we have

$$\alpha = \rho_s(\rho_l)^q = \eta^q \rho_s ,$$

where

$$\eta = \rho_l = \phi_1 \dots \phi_l$$
.

This shows the existence of the integers  $q(\ge 0)$  and  $s(0 \le s \le l-1)$ .

We next show that q and s are unique. Suppose we have  $\alpha = \eta^{q_1} \rho_{s_1} = \eta^{q_2} \rho_{s_2}$  with  $s_1 \leq s_2$ . If  $s_2 > s_1$  then  $q_1 > q_2$  and, appealing to (5.5) and recalling that  $-1 < \overline{\varphi}_i < 0 \ (i \geq 1)$ , we obtain

$$\eta \leqslant \eta^{q_1 - q_2} = \frac{\rho_{s_2}}{\rho_{s_1}} = \prod_{i = s_1 + 1}^{s_2} \left(\frac{-1}{\bar{\phi}_i}\right) < \prod_{i = 1}^{l} \left(\frac{-1}{\bar{\phi}_i}\right) = \eta$$

which is a contradiction. Hence we must have  $s_1 = s_2$ . Then  $\eta^{q_1} = \eta^{q_2}$  and, as  $\eta > 1$ , we must have  $q_1 = q_2$ . This completes the proof of (i).

(ii) From the proof of (i) we see that  $I_n = J = I_0$ , so that  $l \mid n$ , and thus q = n/l and s = 0.

COROLLARY 5.  $\eta = \prod_{i=1}^{l} \phi_i$  is a unit (>1) of  $O_D$  such that every unit  $\varepsilon$  of  $O_D$  is given by  $\varepsilon = \pm \eta^r$ , where r is an integer.  $\eta$  is called the fundamental unit of  $O_D$ .

*Proof.* Let  $\varepsilon$  be a unit of  $O_D$  and let

$$\delta = \begin{cases} \epsilon, & \text{if} \quad \epsilon \geqslant 1, \\ 1/\epsilon, & \text{if} \quad 0 < \epsilon < 1, \\ -1/\epsilon, & \text{if} \quad -1 < \epsilon < 0, \\ -\epsilon, & \text{if} \quad \epsilon \leqslant -1, \end{cases}$$

so that  $\delta$  is a unit of  $O_D$  satisfying  $\delta \geqslant 1$ . Applying Proposition 9 (ii) to  $I_0$  and  $J = \delta I_0$ , we see that  $\delta = \eta^q$ , and so  $\varepsilon = \pm \eta^r$ .

Corollary 5 was first proved by Lagrange in the case of the principal class [3: p. 452] (see also [8]). We see that the theory of periods of reduced, primitive ideals in  $O_D$  not only gives the structure of the group of units of  $O_D$  but also provides the structure of each period (the "infrastructure" of Shanks [7]).

COROLLARY 6. With  $I_0$  a reduced, primitive ideal of  $O_D$ , we have

(i) 
$$\eta = B_{l-1} \phi_0 + B_{l-2}$$
,

(ii) 
$$\eta = A_{l-1} - B_{l-1} \phi_0$$
,

(iii) 
$$l \log \left( \frac{1 + \sqrt{5}}{2} \right) \leq \log \eta < l \log \sqrt{D}$$

Proof. Taking n = Nl(N = 1, 2, ...) in (5.13) we obtain, as  $\phi_{Nl} = \phi_0$ , (6.5)  $\eta^N = B_{Nl-1}\phi_0 + B_{Nl-2}$ .

The assertion (i) is the case N = 1.

From (5.7), (5.9) and (5.13), we obtain for  $n \ge 1$ 

$$\phi_1 \dots \phi_n = \frac{(-1)^{n-1}}{B_{n-1}\phi_0 - A_{n-1}}.$$

Taking n = Nl(N = 1, 2, ...) and recalling that  $\eta \bar{\eta} = (-1)^l$ , we obtain  $\eta^N = -\frac{(\eta \bar{\eta})^N}{B_{Nl-1} \Phi_0 - A_{Nl-1}}$ , so that taking conjugates we deduce

(6.6) 
$$\eta^N = A_{Nl-1} - B_{Nl-1} \bar{\phi}_0.$$

The assertion (ii) is the case N = 1.

From (6.5) and (5.10) we have

$$\eta^N > B_{Nl-1} + B_{Nl-2} \geqslant \left(\frac{1+\sqrt{5}}{2}\right)^{Nl-2} + \left(\frac{1+\sqrt{5}}{2}\right)^{Nl-3} = \left(\frac{1+\sqrt{5}}{2}\right)^{Nl-3},$$

so that

$$\eta > \left(\frac{1+\sqrt{5}}{2}\right)^{1-(1/N)} \qquad (N=1,2,3,...).$$

Letting  $N \rightarrow \infty$ , we obtain

$$\eta \geqslant \left(\frac{1+\sqrt{5}}{2}\right)^{1}$$
,

proving the first equality in (iii).

Finally, as  $\phi_i < \sqrt{D}(i \ge 0)$ , we have

$$\eta = \phi_1 \dots \phi_l < (\sqrt{D})^l$$

proving the second assertion in (iii).

Example 3. (D = 1892) The period of the class containing the ideal  $[1, 21 + \sqrt{473}]$  is

$$\{[1,21+\sqrt{473}], [32,21+\sqrt{473}], [11,11+\sqrt{473}], [32,11+\sqrt{473}]\}.$$

Thus, by Corollary 5, the fundamental unit of  $O_{1892}$  is

$$(21+\sqrt{473}) \left(\frac{21+\sqrt{473}}{32}\right) \left(\frac{11+\sqrt{473}}{11}\right) \left(\frac{11+\sqrt{473}}{32}\right)$$

$$= \frac{1}{11.32^{2}} (21 + \sqrt{473})^{2} (11 + \sqrt{473})^{2}$$

$$= \frac{1}{11.32^{2}} (704 + 32\sqrt{473})^{2}$$

$$= \frac{1}{11} (22 + \sqrt{473})^{2}$$

$$= 87 + 4\sqrt{473}$$

$$= 87 + 2\sqrt{1892}.$$

The period of the class containing the ideal  $[7, 16 + \sqrt{473}]$  is

{[7, 16 + 
$$\sqrt{473}$$
], [16, 19 +  $\sqrt{473}$ ], [19, 13 +  $\sqrt{473}$ ], [23, 6 +  $\sqrt{473}$ ], [8, 17 +  $\sqrt{473}$ ], [31, 15 +  $\sqrt{473}$ ]}

so, by Corollary 5, the fundamental unit of  $O_{1892}$  is also given by

$$\left(\frac{16+\sqrt{473}}{7}\right) \left(\frac{19+\sqrt{473}}{16}\right) \left(\frac{13+\sqrt{473}}{19}\right) \left(\frac{6+\sqrt{473}}{23}\right) \left(\frac{17+\sqrt{473}}{8}\right) \left(\frac{15+\sqrt{473}}{31}\right) \\
= \left(\frac{111+5\sqrt{473}}{16}\right) \left(\frac{29+\sqrt{473}}{23}\right) \left(\frac{91+4\sqrt{473}}{31}\right) \\
= \frac{(349+16\sqrt{473})}{23} \frac{(91+4\sqrt{473})}{31} \\
= 87+4\sqrt{473} = 87+2\sqrt{1892}.$$

We are now in a position to define the distance between two reduced, primitive ideals in the same period.

Definition 13. (Distance between ideals) If I and J are equivalent, reduced, primitive ideals of  $O_D$  then we define the (mutiplicative) distance d(I, J) from I to J by

$$d(I,J) \equiv \rho_s(\operatorname{mod} \times \eta)$$

where  $\rho_s$  is given as in Proposition 9 (i).

It is clear that d(I, I) = 1.

Example 4. (D = 1892) The two reduced, primitive ideals

$$I = [19, 6 + \sqrt{473}]$$
 and  $J = [31, 16 + \sqrt{473}]$ 

of  $O_{1892}$  are equivalent. Applying the Lagrange reduction process to  $[19, 6 + \sqrt{473}]$ , we obtain

$$[19, 6 + \sqrt{473}] \xrightarrow{L} [16, 13 + \sqrt{473}] \xrightarrow{L} [7, 19 + \sqrt{473}] \xrightarrow{L} [31, 16 + \sqrt{473}],$$

so that

$$d(I, J) = \rho_3 = \frac{31}{19} \left( \frac{13 + \sqrt{473}}{16} \right) \left( \frac{19 + \sqrt{473}}{7} \right) \left( \frac{16 + \sqrt{473}}{31} \right)$$

$$= \frac{(13 + \sqrt{473}) (111 + 5\sqrt{473})}{19 \times 16}$$

$$= \frac{238 + 11\sqrt{473}}{19}.$$

On the other hand, applying the Lagrange reduction process to  $[31, 16 + \sqrt{473}]$ , we obtain

$$[31, 16 + \sqrt{473}] \xrightarrow{L} [8, 15 + \sqrt{473}] \xrightarrow{L} [23, 17 + \sqrt{473}] \xrightarrow{L} [19, 6 + \sqrt{473}],$$

so that

$$d(J,I) = \frac{19}{31} \left( \frac{15 + \sqrt{473}}{8} \right) \left( \frac{17 + \sqrt{473}}{23} \right) \left( \frac{6 + \sqrt{473}}{19} \right)$$

$$= \frac{(91 + 4\sqrt{473}) (6 + \sqrt{473})}{31 \times 23}$$

$$= \frac{2438 + 115\sqrt{473}}{31 \times 23}$$

$$= \frac{106 + 5\sqrt{473}}{31}.$$

We note that

$$\left( \frac{238 + 11\sqrt{473}}{19} \right) \left( \frac{106 + 5\sqrt{473}}{31} \right)$$

$$= \frac{51243 + 2356\sqrt{473}}{589}$$

$$= 87 + 4\sqrt{473} = \eta$$

$$\equiv 1 \pmod{\times \eta} .$$

PROPOSITION 10. If I and J are equivalent, reduced, primitive ideals of  $O_D$  then

$$d(J, I) \equiv d(I, J)^{-1} \pmod{\times \eta}.$$

*Proof.* As I and J are in the same period we have  $J = \rho I(\rho \in K^*)$  and  $I = \sigma J(\sigma \in K^*)$ . As  $I = \rho^{-1}J$  we have  $\sigma \equiv \rho^{-1} (\text{mod} \times \eta)$ , which proves Proposition 10.

# 7. Comparison of distances between corresponding ideals in different orders

Let C be a primitive class of the order  $O_{Df^2}$  and let  $\theta(C)$  be the image of C by the mapping  $\theta$  defined in § 3. As an application of the concept of distance described in § 6, we explain how to define a mapping of the period of C into the period of  $\theta(C)$ , which approximately preserves distance.

THEOREM 2. For  $D' = Df^2$  let  $C \in C_{D'}$  and  $\theta(C)$  its image by the surjective homomorphism  $\theta: C_{D'} \to C_D$ .

(i) There exists a mapping  $\tau$  from the period of C into the period of  $\theta(C)$  such that for I and I' in the period of C we have, for a choice of d modulo units,

(7.1) 
$$\frac{d(I,I')}{8f^7D^{3/2}} < d(\tau(I),\tau(I')) < 8f^7D^{3/2}d(I,I').$$

(ii) When f = p (prime) there exists a mapping  $\sigma$  from the period of C into the period of  $\theta(C)$  such that for I and I' in the period of C we have, for a choice d modulo units,

(7.2) 
$$\frac{d(I,I')}{2Dp^2} < d(\sigma(I),\sigma(I')) < 2Dp^2d(I,I').$$

*Proof.* Let  $I = a[1, \phi]$  (a > 0) and  $I' = a'[1, \phi']$  (a' > 0) be two equivalent, reduced, primitive ideals of a class C of  $O_{D'}(D' = Df^2)$  with  $\phi = \frac{b + \sqrt{D'}}{2a}$ 

and 
$$\phi' = \frac{b' + \sqrt{D'}}{2a'}$$
 reduced. Let  $\delta \in K^*$  be such that  $I' = \delta I$ ,  $\delta > 0$ .

(i) If GCD(a, f) = 1 we set  $I_1 = I$ . If GCD(a, f) > 1, from the proof of Lemma 2, we see that there exists an ideal  $I_1 = a_1[1, \phi_1] = \rho I$  in C with
