5. If  $M^{2n}$  is a simply connected compact symplectic manifold, then  $\operatorname{cat}(M) = n = \frac{1}{2} \operatorname{dim}(M)$ . (First, observe that the volume form is not exact since it represents a nontrivial fundamental class of M. Because  $\omega^n/n! = \operatorname{vol}(\operatorname{see}[1], p. 165)$ , the nondegenerate closed 2-form  $\omega$  cannot be exact either. Hence,  $\omega^n$  represents a nontrivial cup-product of length n in **R**-cohomology. By property (4) above,  $\operatorname{cat}(M) \leq (\dim M)/2 = n$ . Hence,

$$n \leq \operatorname{cup}(M) \leq \operatorname{cat}(M) \leq \frac{1}{2} \dim M = n$$

and the result follows.)

# §2. RATIONAL HOMOTOPY AND CATEGORY

The basic reference for this section is [3]. To each space X, Sullivan functorially associated a commutative differential graded algebra (A(X), d) of rational polynomial forms possessing the salient property that integration defines a natural algebra isomorphism between  $H^*(A(X), d)$  and  $H^*(X; \mathbf{Q})$ . Furthermore, the cdga A(X) was shown to contain all the rational homotopy information about X; information which may be gleaned from an associated cdga *minimal model* of A(X).

A cdga  $(\Lambda, d)$  is minimal if (1)  $\Lambda = \Lambda X$ , where  $X = \bigoplus_{i>0} X^i$  is a graded Q-vector space and  $\Lambda X$  denotes that  $\Lambda$  is freely generated by X; that is,  $\Lambda X =$  Symmetric algebra  $(X^{\text{even}}) \otimes$  Exterior algebra  $(X^{\text{odd}})$ . (2) There is a basis for  $X, \{x_{\alpha}\}_{\alpha \in I}$ , so that if I is well ordered by <, then  $dx_{\beta} \in \Lambda_{\alpha<\beta}^+(x_{\alpha})$  $\cdot \Lambda_{\alpha<\beta}^+(x_{\alpha})$ . That is,  $\Lambda$  is constructed by stages and the differentials of  $\beta^{\text{th}}$ stage generators are decomposable in the generators of previous stages.

A minimal model for a space M is a minimal cdga  $\Lambda(M)$  and a cdga map  $\Lambda(M) \rightarrow A(M)$  inducing an isomorphism in cohomology. The fundamental theorem of rational homotopy theory is then (see [4] for example).

THEOREM. Each space M has a minimal model  $\Lambda(M)$  and, furthermore, for nilpotent spaces the stage by stage construction precisely mirrors the rational Postnikov tower with the differential corresponding to the k-invariant.

Recall that a space M is *nilpotent* if its fundamental group  $\pi_1(M)$  is a nilpotent group and the natural action of  $\pi_1(M)$  on  $\pi_n(M)$  (see [10]) is a nilpotent action (see [12]). In particular, any simply connected space or any  $K(\pi, 1)$  with  $\pi$  nilpotent is a nilpotent space. The theorem then says that, for

a nilpotent space, the minimal model is a perfect reflection of the rational homotopy type of the space (eg for i > 1,  $X^i \cong \text{Hom}(\pi_i(M), \mathbf{Q})$ , where  $\pi_i(M)$  is the *i*<sup>th</sup> homotopy group of M). The minimal model  $\Lambda(M)$  is therefore an algebraic version of the **Q**-localization of M. Indeed, a notion of cdga homotopy may be described so that there is a categorical equivalence between the homotopy categories of rational nilpotent spaces and minimal cdga's.

Examples. (1) 
$$\Lambda(S^{2n+1}) = \Lambda(x_{2n+1}), dx = 0.$$
  
(2)  $\Lambda(S^{2n}) = \Lambda(x_{2n}, y_{4n-1}), dy = x^2.$   
(3)  $\Lambda(\mathbb{C}P(n)) = \Lambda(x_2, y_{2n+1}), dy = x^{n+1}.$   
(4)  $\Lambda(T^n) = \Lambda(x_1^1, x_1^2, \cdots, x_1^n), d = 0.$ 

In the next setion we will describe the minimal model of a nilmanifold in terms of the structure of its defining nilpotent group.

In order to understand category in the framework of minimal models, assume for the moment that cat(M) = m. The Whitehead diagram

	M	$\xrightarrow{\Delta}$	$M^{m+1}$
(*)		$\Delta' \Sigma$	$\uparrow j$
			$T^{m+1}(M)$

translates (via Sullivan's categorical equivalence) into a homotopy commutative diagram of minimal cdga's,

$$\begin{array}{rcl} \Lambda X &\leftarrow & (\Lambda X)^{\otimes m+1} \\ (**) & & & & & & & \\ & & & & & & & & \\ & & & & & & & & \\ & & & & & & & & \\ & & & & & & & & \\ & & & & & & & & \\ & & & & & & & & \\ & & & & & & & & \\ & & & & & & & & \\ & & & & & & & & \\ & & & & & & & & \\ & & & & & & & & \\ & & & & & & & & \\ & & & & & & & & \\ & & & & & & & & \\ & & & & & & & \\ & & & & & & & \\ & & & & & & & \\ & & & & & & & \\ & & & & & & & \\ \end{array}$$

where  $\Lambda(M) = \Lambda X$ ,  $\Lambda(M^{m+1}) = (\Lambda X)^{\otimes m+1}$  (since the model of a product is the tensor product of the models),  $\Delta$  is modelled by the (m + 1)-fold multiplication  $\mu$  and  $\Lambda Y = \Lambda(T^{m+1}(M))$ .

Now, however, we may make the following

Definition. The rational category of M (or  $\Lambda(M) = \Lambda X$ ),  $\operatorname{cat}_0(M)$ , is the least m so that (\*\*) exists; that is, there exists  $\rho$  with  $\rho \xi \simeq \mu$ .

Observe that: (1)  $\operatorname{cat}_0(M) \leq \operatorname{cat}(M)$  since any diagram (\*) induces a diagram (\*\*). (2) If M is simply connected, then  $\operatorname{cat}_0(M) = \operatorname{cat}(M_0)$ , where  $M_0$  is the Q-localization of M. This follows since (\*) itself localizes.

### J. OPREA

The definition of  $\operatorname{cat}_0(M)$  would be of little use if this were its only description. The passage from (\*) to (\*\*) simply transfers the difficult problem of obtaining  $\Delta'$  to an (almost) equally difficult problem of obtaining  $\rho$ . However, by understanding the nature of  $\Lambda Y = \Lambda(T^{m+1}(M))$ , a more accessible criterion for  $\operatorname{cat}_0(M)$  may be developed. We first describe  $\Lambda Y$ .

PROPOSITION (2.2 of [3]). A minimal model for the fat wedge is given by a minimal model  $\phi: \Lambda Y \rightarrow \Omega$  for the quotient cdga

$$\Omega = (\Lambda X)^{\otimes m+1} / (\Lambda^+ X)^{\otimes m+1}$$

where  $\Lambda^+ X$  consists of all elements of positive degree. Moreover, if  $\pi: (\Lambda X)^{\otimes m+1} \to \Omega$  is the projection, then any  $\eta: (\Lambda X)^{\otimes m+1} \to \Lambda Y$  with  $\phi \eta \simeq \pi$  is homotopic to the induced map  $\xi$ .

(The existence of  $\eta$  is a consequence of the minimality of  $(\Lambda X)^{\otimes m+1}$ , the fact that  $\phi$  induces an isomorphism of cohomology and cdga obstruction theory. See [4] or [6].)

In some sense, the form of  $\Omega$  is exactly what one would expect viewing the fat wedge as a spatial bound on the "form product" length (as opposed to cuplength). The proof of the proposition relies on various technical results involving  $A(T^{m+1}(M))$ .

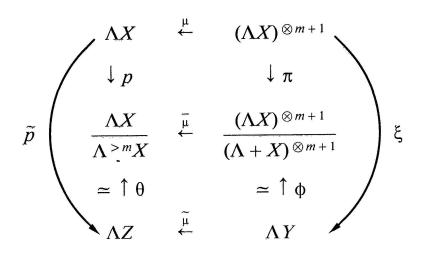

Now let  $\Lambda^{>m}X$  denote the differential ideal of  $\Lambda X$  having additive basis the monomials  $x_{i_1} \cdots x_{i_k}$  with k > m. Consider the projection  $p: \Lambda X \to \Lambda X/\Lambda^{>m}X$  and a minimal model  $\theta: \Lambda Z \to \Lambda X/\Lambda^{>m}X$ . As before (for  $\Lambda Y$ ), minimal model theory provides a lift of  $p, \tilde{p}: \Lambda X \to \Lambda Z$ , with  $\theta \tilde{p} \simeq p$ .

Say that  $\Lambda X$  is a *retract* of  $\Lambda X/\Lambda^{>m}X$  if there exists a cdga map  $r: \Lambda Z \to \Lambda X$  with  $r\tilde{p} \approx 1_{\Lambda X}$ .

We are now in a position to give the rational homotopy criterion for category. We give a proof in one direction and refer to [3] for the other. (Also, we make use of the fact that a cohomology isomorphism  $\theta: A \to B$  induces bijections of cdga homotopy sets  $\theta_*: [\Lambda, A] \xrightarrow{\sim} [\Lambda, B]$  for any minimal  $\Lambda$ .) With the notation above, we have the

THEOREM.  $\operatorname{cat}_0(M) \leq m$  if and only if  $\Lambda X = \Lambda(M)$  is a retract of  $\Lambda X / \Lambda^{>m} X$ .

*Proof.* We only prove the "if" part. Let r denote the retraction,  $\Lambda Z \rightarrow \Lambda X$ , with  $r\tilde{p} \approx 1_{\Lambda X}$ . We have the following homotopy commutative diagram (where  $\bar{\mu}$  is the map induced by  $\mu$  and  $\tilde{\mu}$  is a lift to models),

In order to prove  $\operatorname{cat}_0(M) \leq m$ , we must find  $\rho: \Lambda Y \to \Lambda X$  with  $\rho \xi \simeq \mu$ . We can use the given retraction to do exactly this. Let  $\rho = r\tilde{\mu}$ .

First, observe  $\theta \tilde{p} \mu \simeq p \mu = \bar{\mu} \pi \simeq \bar{\mu} \phi \xi \simeq \theta \tilde{\mu} \xi$ . Because  $\theta$  is a cohomology isomorphism,  $\tilde{p} \mu \simeq \tilde{\mu} \xi$ .

Now,  $\rho \xi = r \tilde{\mu} \xi \simeq r \tilde{p} \mu \simeq 1_{\Lambda X} \mu = \mu$  and we are done.

Of course,  $cat_0(M)$  is, in general, too hard to compute. However, the criterion we have described opens up the possibility of defining weaker invariants which *are* computable. In a sense, the point of this paper is to give an exposition of these weaker invariants in the context of a specific problem of interest to "geometers".

Define  $e_0(M)$  to be the least integer s so that  $p: \Lambda X \to \Lambda X/\Lambda^{>s}X$ induces an injection in cohomology. (This is, in fact, equivalent to requiring  $r: \Lambda Z \to \Lambda X$  to be only a *linear* retraction. The invariant  $e_0(M)$  was first defined by Toomer [9] in terms of the Milnor-Moore spectral sequence.)

Note that if  $r: \Lambda Z \to \Lambda X$  is a retraction, then  $\tilde{p}^*$  is injective and (since  $\theta^*$  is an isomorphism) therefore so is  $p^*$ . Hence, we clearly have

$$e_0(M) \leq \operatorname{cat}_0(M)$$
.

Moreover, when M is a nilpotent space (so that the full power of the minimal model may be utilized) and a manifold (so that Poincaré duality may be exploited), we can identify  $e_0(M)$  in the following manner:

PROPOSITION. If  $M^n$  is a nilpotent manifold with fundamental class  $\tau \in H^n(M; \mathbf{Q})$ , then  $e_0(M)$  is the largest k such that  $\tau$  is represented by a cocycle in  $\Lambda^{\geq k}X$ .

*Proof.* Let  $e_0(M) = s$  and let k be defined by the stated property. If  $\tau$  is represented by a cocycle in  $\Lambda^{>s}X$ , then (for  $p: \Lambda X \to \Lambda X/\Lambda^{>s}X)p^*(\tau) = 0$  and  $p^*$  is therefore not injective. Hence,  $k \leq s$ .

In order to show the reverse inequality  $s \leq k$ , we must show that, for  $p: \Lambda X \to \Lambda X/\Lambda^{>k}X$ ,  $p^*$  is injective. Plainly, by Poincaré duality,  $p^*$  is injective if and only if  $p^*(\tau) \neq 0$ . Hence, we prove this.

Suppose  $p^*(\tau) = 0$ . Let  $\tau$  denote the representing cocycle in  $\Lambda^{\geq k}X$  of the fundamental class  $\tau$ . Let  $p(\tau) = \overline{\tau} \in \Lambda X/\Lambda^{>k}X$  and consider  $\overline{\tau}$  as an element in  $\Lambda^{\leq k}X$ . Now,  $p^*(\tau) = 0$ , so there exists  $\overline{\alpha} \in \Lambda X/\Lambda^{>k}X$  with  $\overline{d\alpha} = \overline{\tau}$ . Consider  $\overline{\alpha} \in \Lambda^{\leq k}X$  as well and note that  $p(d\overline{\alpha}) = \overline{d\alpha} = \overline{\tau}$ . Therefore, in  $\Lambda X$ 

$$d\bar{\alpha} = \bar{\tau} + \Phi$$
, where  $\Phi \in \Lambda^{>k} X$ .

Similarly, of course,  $\tau = \overline{\tau} + \Omega$  for  $\Omega \in \Lambda^{>k}X$  and we obtain,

$$\tau = \bar{\tau} + \Omega = d\bar{\alpha} - \Phi + \Omega$$

with  $\Omega - \Phi \in \Lambda^{>k}X$ . But this means  $\tau$  is cohomologous to  $\Omega - \Phi \in \Lambda^{>k}X$ , contradicting the definition of k.

## §3. NILMANIFOLDS

A nilmanifold M is the quotient of a nilpotent Lie group N by a discrete cocompact subgroup  $\pi$ . The description below follows [7].

It is well known that N is diffeomorphic to some  $\mathbb{R}^n$  and, therefore, M is a  $K(\pi, 1)$ . Furthermore, this entails the fact that  $\pi$  is a finitely generated torsionfree nilpotent group.

On the algebraic side, there is a refinement of the upper central series of  $\pi$ ,

$$\pi \supseteq \pi_2 \supseteq \pi_3 \supseteq \cdots \supseteq \pi_n \supseteq 1$$

with each  $\pi_i/\pi_{i+1} \cong \mathbb{Z}$  whose length is invariant and is called the *rank* of  $\pi$ . So, for  $\pi$  above, rank $(\pi) = n$ .

This description implies that any  $u \in \pi$  has a decomposition  $u = u_1^{x_1} \cdots u_n^{x_n}$ , where  $\langle u_n \rangle = \pi_n, \cdots \langle u_i \rangle = \pi_i/\pi_{i+1}$ . The set  $\{u_1, \cdots u_n\}$  is called a Malcev basis for  $\pi$ . Using this basis the multiplication in  $\pi$  takes the form

$$u_1^{x_1} \cdots u_n^{x_n} u_1^{y_1} \cdots u_n^{y_n} = u_1^{\rho_1(x,y)} \cdots u_n^{\rho_n(x,y)}$$

where

$$\rho_i(x, y) = x_i + y_i + \tau_i(x_1, \cdots x_{i-1}, y_1, \cdots y_{i-1})$$
