ETH-Bibliothek Zürich, E-Periodica, https://www.e-periodica.ch

The remaining candidates are listed below, together with an indication in parenthesis showing that each one (except 505) is excluded by Theorem 2 in Section 2: if N has a prime factor p such that  $p^f \equiv -1 \mod N'$ , where N' is the largest divisor of N relatively prime to p, then there is no (periodic) Barker sequence of length  $4N^2$ .

REMAINING CANDIDATES (excluded by Theorem 2, except N = 505.)

N		N	
$65 = 5 \cdot 13$	$(5^2 \equiv -1 \bmod 13)$	$425=5^2\cdot 17$	$(5^8 \equiv -1 \bmod 17)$
$85 = 5 \cdot 17$	$(17^2 \equiv -1 \bmod 5)$	$445 = 5 \cdot 89$	$(89 \equiv -1 \bmod 5)$
$145 = 5 \cdot 29$	$(29 \equiv -1 \bmod 5)$	$481 = 13 \cdot 37$	$(37^6 \equiv -1 \bmod 13)$
$185 = 5 \cdot 37$	$(37^2 \equiv -1 \bmod 5)$	$485 = 5 \cdot 97$	$(97^2 \equiv -1 \bmod 5)$
$205 = 5 \cdot 41$	$(5^{10} \equiv -1 \bmod 41)$	$493 = 17 \cdot 29$	$(17^2 \equiv -1 \bmod 29)$
$221 = 13 \cdot 17$	$(13^2 \equiv -1 \bmod 17)$	$505 = 5 \cdot 101$	
$265 = 5 \cdot 53$	$(53^2 \equiv -1 \bmod 5)$	$533 = 13 \cdot 43$	$(43^3 \equiv -1 \bmod 13)$
$305 = 5 \cdot 61$	$(5^{15} \equiv -1 \bmod 61)$	$545 = 5 \cdot 109$	$(109 \equiv -1 \bmod 5)$
$325=5^2\cdot 13$	$(5^2 \equiv -1 \bmod 13)$	$565 = 5 \cdot 113$	$(113^2 \equiv -1 \bmod 5)$
$365 = 5 \cdot 73$	$(73^2 \equiv -1 \bmod 5)$	$629 = 17 \cdot 37$	$(37^8 \equiv -1 \bmod 17)$
$377 = 13 \cdot 29$	$(13^7 \equiv -1 \bmod 29)$	$685 = 5 \cdot 137$	$(137^2 \equiv -1 \bmod 5)$

The case  $N = 505 = 5 \cdot 101$  cannot be excluded by Theorem 2, because  $101 \equiv 1 \mod 5$  and  $5^{25} \equiv 1 \mod 101$ . However, 505 can still be excluded by Turyn's Inequality, as observed in [JL]: choosing p = 101 and  $w = 2 \cdot 101^2$ , so that p is trivially semi-primitive modulo w, we would have

$$p\leqslant \frac{v}{w}=2\cdot 5^2=50,$$

a contradiction to the assumed existence of a Barker sequence of length  $4 \cdot 505^2$ .

The first open case is thus  $N = 689 = 13 \cdot 53$ . We have  $53 \equiv 1 \mod 13$  and  $13^{13} \equiv 1 \mod 53$ , so that neither 53 is semi-primitive mod 13, nor 13 is semi-primitive mod 53. The next open case is  $N = 793 = 13 \cdot 61$ .

## 4. The use of the Multiplier Theorem

In this section we give the details of some (typical) non-existence proofs needed to establish the tables, using the multiplier theorem.

Recall that if D is a cyclic difference set with parameters  $(v, k, \lambda)$ , and if  $n = k - \lambda$  is greater than  $\lambda$ , then the group of multipliers of D contains the intersection M in  $(\mathbb{Z}/v\mathbb{Z})^*$  of the subgroups generated by  $l_1, ..., l_r$ , where  $l_1, ..., l_r$  are the prime factors of n.

(1) Parameters ( $v = 181, k = 81, \lambda = 36$ ), Table I with t = 9.

Here,  $n = 3^2 \cdot 5$ , and since  $5 \equiv 3^6 \mod 181$ , the multiplier theorem says that if an abelian difference set exists with these parameters, then 5 is a multiplier. The orbits of the multiplication by 5 in  $\mathbb{Z}/181\mathbb{Z}$  are  $\{0\}$  and 12 orbits of cardinality 15, e.g.

$$\{1, 5, 25, 125, 82, 48, 59, 114, 27, 135, 132, 117, 42, 29, 145\}$$
.

(Note that 181 is a prime number.) No subset of  $G = \mathbb{Z}/181\mathbb{Z}$  of cardinality k = 81 may thus be a union of orbits.

(2) Parameters (v = 4901, k = 2401,  $\lambda = 1176$ ), Table I with t = 49.

Here,  $n = 5^2 \cdot 7^2$ . We have  $25 = 5^2 \equiv 7^6 \mod 4901$ . Therefore, if an abelian difference set exists, m = 25 must be a multiplier. Writing the group  $G = \mathbb{Z}/4901\mathbb{Z}$  as  $G = \mathbb{Z}/13^2\mathbb{Z} \times \mathbb{Z}/29\mathbb{Z}$ , with group operation  $(a, b) \cdot (a', b') = (a + a', b + b')$ , the orbits under multiplication by m = 25 are

$$E = \{(0,0)\}$$

$$U_i = \{(13i, 0), (-13i, 0)\}$$
  $i = 1, 2, 3, 4, 5, 6$ 

 $V_j = \{(j,0), (25j,0), (118j,0), (77j,0), (66j,0), (129j,0), (14j,0), (12j,0), (131j,0), (64j,0), (79j,0), (116j,0), (27j,0), (-j,0), ...\}$ j = 1, ..., 6, each  $V_j$  of cardinality 26.

$$X = \{(0,1), (0,25), (0,16), (0,23), (0,24), (0,20), (0,7)\}$$

$$Y = \{(0,2), (0,21), (0,3), (0,17), (0,19), (0,11), (0,14)\}$$

$$\bar{X} = \{(0, -x) \mid (0, x) \in X\}$$

$$\bar{Y} = \{(0, -y) \mid (0, y) \in Y\}$$

each of cardinality 7.

There are moreover, the 24 orbits  $U_i \cdot X$ ,  $U_i \cdot \bar{X}$ ,  $U_i \cdot Y$ ,  $U_i \cdot \bar{Y}$  of cardinality 14, where

$$A \cdot B = \{a \cdot b \mid a \in A, b \in B\}.$$

Finally, there are 24 orbits  $V_i \cdot X$ ,  $V_i \cdot \bar{X}$ ,  $V_i \cdot Y$ ,  $V_i \cdot \bar{Y}$  of cardinality 182. Contrary to the preceding example, there are many ways of writing the cardinality 2401 of a putative difference set D as a sum of numbers taken from the set of orbit cardinalities.

To ease calculations, we view a subset  $S \subset G$  as the element  $\sum_{s \in S} s$  in the integral group ring. Note that, with this convention, the product  $S \cdot T$  in  $\mathbb{Z}G$  coincides with the element of  $\mathbb{Z}G$  associated with the product set

 $S \cdot T = \{s \cdot t \mid s \in S, t \in T\}$ . A difference set D, if it exists with the above parameters, can be written as

$$D = C + AX + BY + P\bar{X} + Q\bar{Y}$$

where C, as well as A, B, P, Q, is of the form

$$C = \alpha E + \sum_{i=1}^{6} \beta_i U_i + \sum_{j=1}^{6} \gamma_j V_j$$

with coefficients  $\alpha, \beta_1, ..., \beta_6, \gamma_1, ..., \gamma_6$  all equal to 0 or 1.

As in Section 1, D is a difference set if and only if

$$D\bar{D} = 1225 + 1176 \cdot \left(1 + \sum_{i=1}^{6} U_i + \sum_{j=1}^{6} V_j\right) \cdot (1 + X + \bar{X} + Y + \bar{Y}).$$

Now, writing  $G = G_1 \times G_2$  as above,  $G_1 = \mathbb{Z}/13^2\mathbb{Z}$ ,  $G_2 = \mathbb{Z}/29\mathbb{Z}$ , let  $\pi : \mathbb{Z}G \to \mathbb{Z}/3$  be the projection on the group ring of  $G_1$ . We have  $\pi X = \pi \bar{X} = \pi Y = \pi \bar{Y} = 7$ , and reducing modulo 7,

$$\pi(D\bar{D}) = C\bar{C} = 0 \text{ in } \mathbf{F}_7 G_1.$$

The involution of **Z**G, sending (a, b) to  $\overline{(a, b)} = (-a, -b)$ , is the identity on  $U_i, V_i$ :

$$\bar{U}_i = U_i, \quad \bar{V}_j = V_j.$$

Therefore  $\bar{C}=C$  and  $C^2=0$  in  $\mathbb{F}_7G_1$ . However,  $\mathbb{F}_7G_1$ , where  $G_1$  is of order 13<sup>2</sup>, prime to 7, is a semi-simple algebra and does not contain any nilpotent element. It follows that C=0 in  $\mathbb{F}_7G_1$ . Since the coefficients of  $C=\alpha E+\sum_{i=1}^6\beta_iU_i+\sum_{j=1}^6\gamma_iV_j$  are all 0 or 1, this implies C=0 in  $\mathbb{Z}G_1$ , i.e.

$$D = AX + BY + P\bar{X} + Q\bar{Y},$$

and  $\pi D = 7 \cdot S$  with

$$S = r + \sum_{i=1}^{6} s_i U_i + \sum_{j=1}^{6} t_j V_j$$
,

where S = A + B + P + Q. Thus, all coefficients  $r, s_1, ..., s_6, t_1, ..., t_6$  are non-negative integers  $\leq 4$ .

Again  $\pi(D\bar{D}) = 1225 + 1176 \cdot (1 + \sum U_i + \sum V_j) \cdot 29$ . Therefore,

$$S^2 = 25 + 696 \cdot \left(1 + \sum_{i=1}^6 U_i + \sum_{j=1}^6 V_j\right).$$

With our (abuse of) notation, we set  $G_1 = 1 + \sum U_i + \sum V_j$ . Then,  $G_1^2 = 169 \cdot G_1$ . Thus, we see that

$$S = \pm (5 + 2G_1)$$

are solutions of  $S^2 = 25 + 696 \cdot G_1$ . We claim that there is no other. This will clearly finish the non-existence proof since  $r \leq 4$ . Note the decomposition

$$\mathbf{Q}G_1 = \mathbf{Q} \times \mathbf{Q}(\zeta_{13}) \times \mathbf{Q}(\zeta_{169})$$

of the algebra  $QG_1$  as a product of fields, where  $\zeta_{13}$  is a primitive 13-th root of unity, and  $\zeta_{169}$  a primitive 169-th root of unity.

The element  $G_1 = \sum_{k=0}^{168} z^k \in \mathbb{Z}G_1$  corresponds on the right hand side to (169,0,0) since  $\zeta_{13}$  and  $\zeta_{169}$  are roots of the polynomial  $\sum_{k=0}^{168} X^k$ . It follows that  $S^2 = (343^2, 5^2, 5^2)$ . Hence, any solution  $Z \in \mathbb{Z}G_1$  of the equation  $Z^2 = 25 + 696G_1$  must correspond to  $(\pm 343, \pm 5, \pm 5)$ . Changing Z to -Z, we can assume  $Z = (343, \pm 5, \pm 5)$ . Now, the diagrams

$$\mathbf{Z}G_1 \rightarrow \mathbf{Z}[\zeta_{13}]$$

$$\downarrow \qquad \qquad \downarrow$$

$$\mathbf{Z} \rightarrow \mathbf{F}_{13}$$

and

$$\mathbf{Z}G_1 \rightarrow \mathbf{Z}[\zeta_{169}]$$

$$\downarrow \qquad \qquad \downarrow$$

$$\mathbf{Z} \rightarrow \mathbf{F}_{13}$$

where the right vertical arrows send  $\zeta_{13}$ , resp.  $\zeta_{169}$  to  $1 \in \mathbf{F}_{13}$ , are commutative. Since 5 is not congruent to -5 modulo 13, and 343 maps to  $+5 \in \mathbf{F}_{13}$ , we see that Z = (343, 5, 5) = S.

(3) Parameters (v = 13613, k = 6724,  $\lambda = 3321$ ), Table I with t = 82.

This case is as simple as case (1). Indeed,  $n = 3403 = 41 \cdot 83$ . Since  $41 \equiv 83^3 \mod 13613$ , it follows from the multiplier theorem that if a cyclic difference set D with parameters (13613, 6724, 3321) existed, then 41 would be a multiplier, and D could be taken to be a union of orbits under multiplication by 41 on the cyclic group  $\mathbb{Z}/13613\mathbb{Z}$ .

The order of 41 modulo 13613 is 3403, and beside the one-point orbit  $\{0\}$ , there are 4 orbits X, iX,  $i^2X$ ,  $i^3X$  each of cardinality 3403, where

$$X = \{1, 41, 1681, ..., 13281\}$$

and i is a square root of  $-1 \mod 13613$ , e.g. i = 165. Note that 13613 is a prime number.

However, 6724 is not of the form  $n_0 + 3403n_1$  with  $n_0 = 0$  or 1 and  $0 \le n_1 \le 4$ . No difference set can therefore have the above parameters. (4), (5), (6) Parameters  $(v, k, \lambda) = (3^3, 13, 6)$ ,  $(3^5, 121, 60)$  and  $(7^3, 171, 85)$ 

of Table II, with n = 7,61 and 86 respectively.

More generally, we will consider the case

$$(v,k,\lambda) = \left(p^{2t+1}, \frac{p^{2t+1}-1}{2}, \frac{p^{2t+1}-3}{4}\right),$$

where p is a prime  $\equiv 3 \mod 4$ .

order  $5 \cdot 11$  modulo  $11^3$ .

We have  $n = k - \lambda = \frac{p^{2t+1} + 1}{4}$ . Let  $l_1, ..., l_r$  be the primes dividing n.

The group of multipliers for a putative difference set D with the above parameters contains the intersection M in  $(\mathbf{Z}/v\mathbf{Z})^*$  of the subgroups generated by  $l_1, ..., l_r$ . Since  $(\mathbf{Z}/v\mathbf{Z})^*$  is cyclic, M is the unique subgroup of  $(\mathbf{Z}/v\mathbf{Z})^*$  whose order is the greatest common divisor of the orders  $q_1, ..., q_r$  of  $l_1, ..., l_r$  in  $(\mathbf{Z}/v\mathbf{Z})^*$ . We will now assume that the orders  $q_1, ..., q_r$  of the prime factors  $l_1, ..., l_r$  of  $n = k - \lambda$  in  $(\mathbf{Z}/v\mathbf{Z})^*$  are all divisible by  $p^{t+1}$ .

THEOREM. There is no cyclic difference set with parameters

$$(v,k,\lambda) = \left(p^{2t+1},\frac{p^{2t+1}-1}{2},\frac{p^{2t+1}-3}{4}\right),$$

where p is a prime  $\equiv 3 \mod 4$ , provided that the orders  $q_1, ..., q_r$  of the prime factors  $l_1, ..., l_r$  of  $n = k - \lambda$  in  $(\mathbb{Z}/v\mathbb{Z})^*$  are all divisible by  $p^{t+1}$ .

Note that the hypotheses of the theorem above are satisfied for the three examples we have in mind. (Cases n = 7,61 and 86 in Table II.)

- (1) n = 7: p = 3, t = 1, and 7 is of order  $3^2$  modulo 27;
- (2) n = 61: p = 3, t = 2, and 61 is of order  $3^4$  modulo 243;
- (3) n = 86: p = 7, t = 1, and 2 is of order  $3 \cdot 7^2$  modulo 343, 43 is of order  $7^2$  modulo 343.

As expected, the hypothesis on the orders of the prime factors of n is not satisfied in general. It fails for instance for p = 11, t = 1: here  $n = \frac{11^3 + 1}{4}$  = 333 = 3<sup>2</sup> · 37 and whereas 37 is of order 5 · 11<sup>2</sup> modulo 11<sup>3</sup>, 3 is only of

However, failure of the hypothesis seems fairly rare: the next example with t = 1 occurs for p = 3511. Note that 3511 is special for another reason: it satisfies the congruence  $2^{p-1} \equiv 1 \mod p^2$ , the only other known solution being the famous p = 1093. Such prime numbers are known in the literature as Wieferich prime numbers.

The behaviour of the orders of the prime factors of  $n = \frac{p^{2t+1} + 1}{4}$  in  $(\mathbb{Z}/p^{2t+1}\mathbb{Z})^*$  is probably a difficult question.

*Proof of the Theorem*. The hypothesis on the orders  $q_1, ..., q_r$  means that  $m = 1 + p^t$ , which generates the subgroup of order  $p^{t+1}$  in  $(\mathbf{Z}/p^{2t+1}\mathbf{Z})^*$ , is contained in all the subgroups  $< l_1 > , ..., < l_r >$  of  $(\mathbf{Z}/p^{2t+1}\mathbf{Z})^*$ , and thus is a multiplier of any candidate difference set  $D \subset \mathbf{Z}/p^{2t+1}\mathbf{Z}$  with the above parameters.

What are the orbits of multiplication by  $m = 1 + p^t$  in the ring  $\mathbb{Z}/p^{2t+1}\mathbb{Z}$ ? If  $a_i = i \cdot p^{t+1}$ , then  $a \cdot m \equiv a \mod p^{2t+1}$ . Hence, there are  $p^t$  fixed points  $a_0 = 0, a_1, ..., a_{p^t-1}$ .

More generally, if  $a_{i,j} = ip^{t-j+1}$  with  $1 \le i \le p^t - 1$  and gcd(i,p) = 1, j = 1, ..., t+1, then  $a_{i,j}$  produces an orbit  $\{a_{i,j}m^{\vee}\}_{\vee=0,...,p^{j}-1}$  of length  $p^j$ . Here, we use the formula

$$(1+p^t)^{p^s} \equiv 1 + p^{t+s} \mod (p^{t+s+1})$$

easily proved (for p odd) by induction on s, and which implies that m has (multiplicative) order  $p^j$  modulo  $p^{t+j}$ .

The orbits  $A_{i,j}$  of  $a_{i,j}$  with  $i \in \mathbb{Z}/p^t\mathbb{Z}$  for j = 0  $(a_{i,0} = a_i)$ , and  $i \in (\mathbb{Z}/p^t\mathbb{Z})^*$  for j = 1, ..., t + 1 are easily verified to be disjoint. Together, they sweep out

$$p^{t} + \sum_{j=1}^{t+1} (p-1)p^{t-1} p^{j} = p^{2t+1}$$

elements of the group  $\mathbb{Z}/p^{2t+1}\mathbb{Z}$ . Hence,  $A_{i,j}$  with  $i \in \mathbb{Z}/p^t\mathbb{Z}$  for j=0  $(a_{i,0}=a_i)$ , and  $i \in (\mathbb{Z}/p^t\mathbb{Z})^*$  for j=1,...,t+1 is the complete collection of orbits under multiplication by  $m=1+p^t$  in  $\mathbb{Z}/p^{2t+1}\mathbb{Z}$ . At this point, it may be more convenient to write the group ring of  $\mathbb{Z}/p^{2t+1}\mathbb{Z}$  as  $\mathbb{Z}[x]/(x^{p^{2t+1}}-1)$ . Identifying a subset  $A \subset \mathbb{Z}/p^{2t+1}\mathbb{Z}$  with the sum of the corresponding elements  $\sum_{a \in A} a$  in the group ring, the orbits  $A_{i,j}$  can then be written as

$$A_{i,j} = \sum_{v=0}^{p^j-1} x^{ip^{t-j+1}m^v}.$$

If a difference set D with the above parameters exists, it must be of the form

$$D = \sum_{i \in S_0} x^{ip^{t+1}} + \sum_{j=1}^{t+1} \sum_{i \in S_j} A_{i,j}$$

where  $S_0 \subset \mathbf{Z}/p^t\mathbf{Z}$  and  $S_j \subset (\mathbf{Z}/p^t\mathbf{Z})^*$  for j = 1, ..., t + 1. Now, let  $\pi : \mathbf{Z}[x]/(x^{p^{2t+1}}-1) \to \mathbf{Z}[y]/(y^p-1)$  be the projection of the group ring of  $\mathbf{Z}/p^{2t+1}\mathbf{Z}$  onto the group ring of the cyclic group of order p. We have  $\pi(x) = y$  and

$$\pi A_{i,j} = p^i$$
 for  $j = 0, 1, ..., t$   
 $\pi A_{i,t+1} = p^{t+1} \cdot y^i$  for  $i \in (\mathbf{Z}/p^t\mathbf{Z})^*$ .

It follows that

$$\pi D = s_0 + p s_1 + \cdots + p^t s_t + p^{t+1} \left( \sum_{i \in S_{t+1}} y^i \right),$$

where  $s_i = \operatorname{Card}(S_i)$ .

Let  $N = s_0 + ps_1 + \cdots + p^t s_t$  and  $a_{\mu} = \operatorname{Card}\{i \mid i \in S_{t+1}, i \equiv \mu \mod p\}$ , then

$$\pi D = N + p^{t+1} Y,$$

with  $Y = \sum_{\mu=1}^{p-1} a_{\mu} y^{\mu}$ . (Note that  $a_0$  is indeed 0 as  $S_{t+1} \subset (\mathbf{Z}/p^t\mathbf{Z})^*$ .) Therefore  $\pi(D\bar{D}) = \pi(D)\overline{\pi(D)}$  has the form

$$\pi(D\bar{D}) = N^2 + Np^{t+1} \sum_{\mu=1}^{p-1} a_{\mu}(y^{\mu} + y^{-\mu}) + p^{2t+2}Y\bar{Y}.$$

On the other hand the condition for D being a difference set yields, after applying  $\pi$ ,

$$\pi(D\bar{D}) = \frac{p^{2t+1}+1}{4} + \frac{p^{2t+1}-3}{4} p^{2t} \left(\sum_{\mu=0}^{p-1} y^{\mu}\right).$$

We will reach a contradiction by comparing the constant terms (coefficient of 1 in  $\mathbb{Z}[y]/(y^p-1)$ ) in the two expressions for  $\pi(D\bar{D})$ :

$$N^2 + p^{2t+2} \sum_{\mu=1}^{p-1} a_{\mu}^2 = \frac{p^{2t+1}+1}{4} + \frac{p^{2t+1}-3}{4} p^{2t}.$$

Note that  $k = \text{Card}(D) = N + p^{t+1}s_{t+1}$ , where  $s_{t+1} = \text{Card}(S_{t+1})$ , and hence  $N = \frac{p^{2t+1} - 1}{2} - p^{t+1}s_{t+1}$ . Substituting this in the above equation,

we get

$$4s_{t+1} \equiv 3p^{t-1}(p-1) \mod p^{t+1}$$
.

Writing  $4s_{t+1} = 3p^{t-1}(p-1) + z \cdot p^{t+1}$  for  $z \in \mathbb{Z}$ , we observe that  $p \equiv 3 \mod 4$  implies  $z \equiv 2 \mod 4$ , and so  $2p^{t+1} \leq |z \cdot p^{t+1}|$ . But,  $s_{t+1} = \operatorname{Card}(S_{t+1}) \leq p^{t-1}(p-1)$ , since  $S_{t+1} \subset (\mathbb{Z}/p^t\mathbb{Z})^*$ . It follows that

$$|z \cdot p^{t+1}| \le |4s_{t+1} - 3p^{t-1}(p-1)| \le 3p^{t-1}(p-1) < 2p^{t+1} \le |z \cdot p^{t+1}|.$$

We have reached the desired contradiction, i.e. no cyclic difference set with parameters  $\left(p^{2t+1}, \frac{p^{2t+1}-1}{2}, \frac{p^{2t+1}-3}{4}\right)$  exists if the orders of the

prime factors of  $n = \frac{p^{2t+1}+1}{4}$  in  $(\mathbf{Z}/p^{2t+1}\mathbf{Z})^*$  are all divisible by  $p^{t+1}$ .  $\square$ 

(7) Parameters (v = 399, k = 199,  $\lambda = 99$ ), Table II. This is the last item in Table II, corresponding to  $n = k - \lambda = 100$ .

Since  $4 = 2^2 \equiv 5^8 \mod 399$ , it follows that 4 must be a multiplier of any abelian difference set D with the above parameters.

Writing Z/399Z as a direct product

$$\mathbf{Z}/399\mathbf{Z} = \mathbf{Z}/3\mathbf{Z} \times \mathbf{Z}/7\mathbf{Z} \times \mathbf{Z}/19\mathbf{Z} ,$$

and accordingly writing the elements of  $\mathbb{Z}/399\mathbb{Z}$  as triples g = (x, y, z),  $x \in \mathbb{Z}/3\mathbb{Z}$ ,  $y \in \mathbb{Z}/7\mathbb{Z}$ ,  $z \in \mathbb{Z}/19\mathbb{Z}$ , we have the following orbits of the multiplication by 4 in  $\mathbb{Z}/399\mathbb{Z}$ : all monomials XYZ, with  $X \in \{1, U, \overline{U}\}$ ,  $Y \in \{1, V, \overline{V}\}$ ,  $Z \in \{1, W, \overline{W}\}$ , where

$$1 = \{(0,0,0)\}$$

$$U = \{(1,0,0)\}$$

$$V = \{(0, 1, 0), (0, -3, 0), (0, 2, 0)\}$$

$$W = \{(0,0,1), (0,0,4), (0,0,-3), (0,0,7), (0,0,9), (0,0,-2), (0,0,-8), (0,0,6), (0,0,5)\},$$

and bar denotes the conjugate, i.e. if  $C \subset \mathbb{Z}/v\mathbb{Z}$ , then  $\overline{C} = \{-g \mid g \in C\}$ .

All orbits, except 1, U,  $\bar{U}$  have cardinality divisible by 3. Since  $k = 199 \equiv 1 \mod 3$ , any putative difference set D can be assumed to contain a single one-point orbit 1, U or  $\bar{U}$ . Multiplying D by U or  $\bar{U}$  if necessary, we may assume that

$$D = 1 + A \cdot V + B \cdot \bar{V} + P \cdot W + Q \cdot \bar{W},$$

where

$$A = \alpha_0 + \alpha_1 U + \alpha_2 \overline{U}, \ 0 \leqslant \alpha_i \leqslant 1,$$
  
 $B = \beta_0 + \beta_1 U + \beta_2 \overline{U}, \ 0 \leqslant \beta_i \leqslant 1,$ 

and P, Q are polynomials in  $U, \bar{U}$  and  $V, \bar{V}$ .

We first show that A and B must be 0. Let  $a = \alpha_0 + \alpha_1 + \alpha_2$ ,  $b = \beta_0 + \beta_1 + \beta_2$ , and let  $\pi: \mathbb{Z}/399\mathbb{Z} \to \mathbb{Z}/7\mathbb{Z}$  be the projection on the second factor.

We indulge in various abuses of notation: we write  $\pi$  for the group ring projection as well and denote  $\pi V$  again by V. Note that  $\pi U = \pi \bar{U} = 1$ ,  $\pi W = \pi \bar{W} = 9$ . Then  $\pi D \equiv 1 + aV + b\bar{V} \mod 9$ , a congruence in the group ring of  $\mathbb{Z}/7\mathbb{Z}$ .

Since  $D\bar{D} = 100 + 99 \cdot (1 + U + \bar{U}) (1 + V + \bar{V}) (1 + W + \bar{W})$ , the equation expressing that D is a difference set with the required parameters, we have  $D\bar{D} \equiv 1 \mod 9$ .

Consequently, using

$$V\bar{V} = 3 + V + \bar{V}$$
,  $V^2 = V + 2\bar{V}$ ,  $\bar{V}^2 = 2V + \bar{V}$ ,

we get, expanding  $\pi(D\bar{D}) = \pi(D)\pi(\bar{D})$ , and after collecting terms,

$$3(a^2 + b^2) + (a + b + a^2 + b^2 + 3ab) (V + \overline{V}) \equiv 0 \mod 9$$
.

Thus,  $a^2 + b^2 \equiv 0 \mod 3$ , and this means  $a \equiv b \equiv 0 \mod 3$ . But then  $a^2 + b^2 + 3ab \equiv 0 \mod 9$ , and so we must also have

$$a + b \equiv 0 \mod 9$$
,

after looking at the coefficient of  $V + \bar{V}$  in the above congruence.

Since  $0 \le a \le 3$ ,  $0 \le b \le 3$ , this means a = b = 0 and therefore A = B = 0. Any difference set D with parameters (399, 199, 99) can therefore be assumed to have the form

$$D=1+P\cdot W+Q\cdot \bar{W}.$$

Plugging  $D = 1 + P \cdot W + Q \cdot \overline{W}$  into the equation

$$D\bar{D} = 100 + 99(1 + U + \bar{U})(1 + V + \bar{V})(1 + W + \bar{W})$$

and using the multiplication table

$$W\bar{W} = 9 + 4(W + \bar{W}), W^2 = 4W + 5\bar{W},$$

we get

$$1 + 9(P\bar{P} + Q\bar{Q}) = 100 + 99(1 + U + \bar{U})(1 + V + \bar{V})$$

 $P + \bar{Q} + 4(P\bar{P} + Q\bar{Q}) + 5\bar{P}Q + 4P\bar{Q} = 99(1 + U + \bar{U}) (1 + V + \bar{V})$ , where

$$P = p_0 + p_1 U + p_2 \bar{U} + (p_3 + p_4 U + p_5 \bar{U}) V + (p_6 + p_7 U + p_8 \bar{U}) \bar{V}$$

$$Q = q_0 + q_1 U + q_2 \bar{U} + (q_3 + q_4 U + q_5 \bar{U}) V + (q_6 + q_7 U + q_8 \bar{U}) \bar{V}$$

with  $0 \le p_i, q_i \le 1$ , for i = 0, ..., 8.

The first equation gives

$$P\bar{P} + Q\bar{Q} = 11 + 11(1 + U + \bar{U})(1 + V + \bar{V}).$$

Substituting in the second equation, we get

(\*) 
$$P + \bar{Q} + 5\bar{P}Q + 4P\bar{Q} = -44 + 55(1 + U + \bar{U})(1 + V + \bar{V})$$
.

Since  $U\bar{U}=1$ ,  $U^2=\bar{U}$  and  $V\bar{V}=3+V+\bar{V}$ ,  $V^2=V+2\bar{V}$ , the constant terms in  $\bar{P}Q$  and  $P\bar{Q}$  are equal to  $\sum_{i=0}^2 p_i q_i + 3\sum_{j=3}^8 p_j q_j = c$ , say. Hence, equating constant terms in the above equation (\*), we must have

$$p_0 + q_0 + 9c = 11.$$

The only solution to this equation with all  $p_i$ ,  $q_i$  being 0 or 1, is  $p_0 = q_0 = 1$ ,  $p_i = q_i = 0$  for i = 1, ..., 8. This means P = Q = 1, contradicting (\*).

# 5. Comments on the examples in Tables II

Difference sets with parameters  $(v, k, \lambda) = (4n - 1, 2n - 1, n - 1)$  are usually called *Hadamard difference sets*. Our purpose here is to discuss the classification of these cyclic difference sets for  $2 \le n \le 100$ .

In many cases where v = 4n - 1 is a prime p, the quadratic residue difference set, which we denote by QR(p) is unique for the given values of the parameters. This is obviously the case if the multiplier m has order  $k = \frac{1}{2}(v-1)$  in  $(\mathbb{Z}/v\mathbb{Z})^*$ . Indeed, in this case, there are exactly 3 orbits of multiplication by m in  $\mathbb{Z}/v\mathbb{Z}$ , namely  $1 = \{0\}$ ,  $M = \{1, m, m^2, ..., m^{k-1}\}$  and  $M = \{-1, -m, ..., -m^{k-1}\}$ . Thus the only choice for D is D = M or D = M, which are isomorphic under conjugation  $\sigma: \mathbb{Z}/v\mathbb{Z} \to \mathbb{Z}/v\mathbb{Z}$ ,  $\sigma(a) = -a$ .

In our Table II, this situation happens for n = 3, 5, 6, 12, 15, 17, 18, 20, 21, 27, 33, 35, 41, 42, 45, 48, 53, 57, 60, 63, 66, 68, 77, 87, 90 and 96.

The remaining cases where v = 4n - 1 is a prime p (for  $2 \le n \le 100$ ) have been shown to lead to a single difference set, namely QR(p), by machine enumeration of the various choices of D as a union of orbits under multiplication by a multiplier m. This includes the cases n = 26 (multiplier 8), n = 38 (multiplier 19), n = 50 (multiplier 5), n = 78 (multiplier 13), n = 83 (multiplier 83), and n = 95 (multiplier 5). By far, the most difficult case (for the machine) occurs with n = 38, which required the examination of 37 442 160 combinations of multiplier orbits.
