First consider the case where h has a unique ternary expansion, which is necessarily infinite. Then $S(k) = 2^{c(k)}$. To see, this, set $h = \sum a_n/3^n$ where $a_n = 0, 1$, or 2 ($n = 1, 2, 3, \dots$), $a_n \neq 0$ for infinitely many n and $a_n \neq 2$ for infinitely many n . We wish to count the number of representations $h = x + y$ where $x, y \in \frac{1}{2} C$; i.e., $x = \sum \varepsilon_n/3^n$, $y = \sum \varepsilon'_n/3^n$ and $\varepsilon_n, \varepsilon'_n = 0$ or 1 . Now if $a_n = 0$, clearly $\varepsilon_n = \varepsilon'_n = 0$. Also if $a_n = 2$, $\varepsilon_n = \varepsilon'_n = 1$. However if $a_n = 1$, we can have $\varepsilon_n = 1$ and $\varepsilon'_n = 0$ or we can have $\varepsilon_n = 0$ and $\varepsilon'_n = 1$. Hence there are $2^{c(k)}$ choices for (x, y) (uncountable if $c(k)$ is infinite).

Next consider the case where h has two ternary expansions. Then they are necessarily of the form

$$h = .a_1 a_2 \dots a_r 22 \dots = .a_1 a_2 \dots a_{r-1} b_r$$

where $a_1, a_2, \dots, a_{r-1} = 0, 1, 2$, $a_r = 0$ or 1 and $b_r = a_r + 1$. Then using the ideas in the last paragraph and keeping in mind there are two counts (one for each representation of h), we have:

$$S(k) = \begin{cases} 3(2^{c(k)}) & \text{if } a_r = 0 \\ 3(2^{c(k)-1}) & \text{if } a_r = 1 \end{cases}.$$
