If Y is homotopy-equivalent to $\mathbf{R}P^3 \# \mathbf{R}P^3$ then $\pi_1(Y)$ is amenable, which is a contradiction. So we must be in the second case. Using Property 3, we may assume that $Y = Y'$. Then as Y is prime, it follows from [24, Chapter 1] that either $Y = S^1 \times D^2$ or Y has incompressible (or empty) boundary. If $Y = S^1 \times D^2$ then $\pi_1(Y)$ is amenable. If Y has incompressible (or empty) boundary then from [21, Theorem 0.1.5], $\alpha_2(Y) \leq 2$ unless Y is a closed 3-manifold with an \mathbf{R}^3 , $\mathbf{R} \times S^2$ or Sol geometric structure. In the latter cases, Γ is amenable. Thus in any case, we get a contradiction. \square

The next proposition gives examples of big groups.

PROPOSITION 14.

1. *A product of two nonamenable groups is big.*
2. *If Y is a closed nonpositively-curved locally symmetric space of dimension greater than three, with no Euclidean factors in \tilde{Y} , then $\pi_1(Y)$ is big.*

Proof. 1. Suppose that $\Gamma = \Gamma_1 \times \Gamma_2$ with Γ_1 and Γ_2 nonamenable. Then Γ is nonamenable. Let K_1 and K_2 be presentation complexes with fundamental groups Γ_1 and Γ_2 , respectively. Put $K = K_1 \times K_2$. Then $\Gamma = \pi_1(K)$. Let $\Delta_p(\tilde{K})$, $\Delta_p(\tilde{K}_1)$ and $\Delta_p(\tilde{K}_2)$ denote the Laplace-Beltrami operator on p -cochains on \tilde{K} , \tilde{K}_1 and \tilde{K}_2 , respectively, as defined in Subsection 5.2 below. Then

$$(5.4) \quad \inf(\sigma(\Delta_1(\tilde{K}))) = \min(\inf(\sigma(\Delta_1(\tilde{K}_1))) + \inf(\sigma(\Delta_0(\tilde{K}_2))), \\ \inf(\sigma(\Delta_0(\tilde{K}_1))) + \inf(\sigma(\Delta_1(\tilde{K}_2)))) > 0.$$

Using Proposition 11, the first part of the proposition follows.

2. If \tilde{Y} is irreducible then part 2. of the proposition follows from the second remark after Proposition 7. If \tilde{Y} is reducible then we can use an argument similar to (5.4). \square

REMARK. Let Γ be an infinite finitely-presented discrete group with Kazhdan's property T. From [6, p. 47], $H^1(\Gamma; \ell^2(\Gamma)) = 0$. This implies that Γ is nonamenable and $b_1^{(2)}(\Gamma) = 0$. We do not know if it is necessarily true that $\alpha_2(\Gamma) = \infty^+$.

5.2 TWO AND THREE DIMENSIONS

In this subsection we relate the zero-in-the-spectrum question to a question in combinatorial group theory. Let K be a finite connected 2-dimensional

CW-complex. Let \tilde{K} be its universal cover. Let $C^*(\tilde{K})$ denote the Hilbert space of square-integrable cellular cochains on \tilde{K} . There is a cochain complex

$$(5.5) \quad 0 \longrightarrow C^0(\tilde{K}) \xrightarrow{d_0} C^1(\tilde{K}) \xrightarrow{d_1} C^2(\tilde{K}) \longrightarrow 0.$$

Define the Laplace-Beltrami operators by $\Delta_0 = d_0^* d_0$, $\Delta_1 = d_0 d_0^* + d_1^* d_1$ and $\Delta_2 = d_1 d_1^*$. These are bounded self-adjoint operators and so we can talk about zero being in the spectrum of \tilde{K} .

PROPOSITION 15. *Zero is not in the spectrum of \tilde{K} if and only if $\pi_1(K)$ is big and $\chi(K) = 0$.*

Proof. Suppose that zero is not in the spectrum of \tilde{K} . From the analog of Proposition 11, Γ must be big. Furthermore, from Properties 1 and 7, $\chi(K) = 0$.

Now suppose that $\pi_1(K)$ is big and $\chi(K) = 0$. From the analog of Proposition 11, $0 \notin \sigma(\Delta_0)$ and $0 \notin \sigma(\Delta_1)$. In particular, $\text{Ker}(\Delta_0) = \text{Ker}(\Delta_1) = 0$. From Properties 1 and 7, $\text{Ker}(\Delta_2) = 0$. As $C^2(\tilde{K}) = \text{Ker}(\Delta_2) \oplus \overline{d_1 C^1(\tilde{K})}$, we conclude that $0 \notin \sigma(\Delta_2)$. \square

Let Γ be a finitely-presented group. Consider a fixed presentation of Γ consisting of g generators and r relations. Let K be the corresponding presentation complex. Then $\chi(K) = 1 - g + r$. Thus zero is not in the spectrum of \tilde{K} if and only if $\pi_1(K)$ is big and $g - r = 1$.

Recall that the *deficiency* $\text{def}(\Gamma)$ is defined to be the maximum, over all finite presentations of Γ , of $g - r$. If $b_1^{(2)}(\Gamma) = 0$ then from the equation

$$(5.6) \quad \chi(K) = 1 - g + r = b_0^{(2)}(\Gamma) - b_1^{(2)}(\Gamma) + b_2^{(2)}(K),$$

we obtain $\text{def}(\Gamma) \leq 1$. This is the case, for example, when Γ is big or when Γ is amenable [5].

As any finite connected 2-dimensional CW-complex is homotopy-equivalent to a presentation complex, it follows from Proposition 15 that the answer to the zero-in-the-spectrum question is “yes” for universal covers of such complexes if and only if the following conjecture is true.

CONJECTURE 1. *If Γ is a big group then $\text{def}(\Gamma) \leq 0$.*

REMARK. If $\pi_1(K)$ has property T then the ordinary first Betti number of K vanishes [6], and so $\chi(K) = 1 + b_2(K) > 0$. Thus zero lies in the spectrum of \tilde{K} .

Now let Y be a 3-manifold satisfying the conditions of Proposition 13. If $\partial Y \neq \emptyset$, we define Δ_p on \tilde{Y} using absolute boundary conditions on $\partial\tilde{Y}$.

PROPOSITION 16. *Zero lies in the spectrum of \tilde{Y} .*

Proof. This is a consequence of Propositions 11 and 13. \square

5.3 FOUR DIMENSIONS

In this subsection we relate the zero-in-the-spectrum question to a question about Euler characteristics of closed 4-dimensional manifolds.

If M is a Riemannian 4-manifold then the Hodge decomposition gives

$$\begin{aligned}
 (5.7) \quad \Lambda^0(M) &= \text{Ker}(\Delta_0) \oplus \Lambda^0(M)/\text{Ker}(d), \\
 \Lambda^1(M) &= \text{Ker}(\Delta_1) \oplus \overline{d\Lambda^0(M)} \oplus \Lambda^1(M)/\text{Ker}(d), \\
 \Lambda^2(M) &= \text{Ker}(\Delta_2) \oplus \overline{d\Lambda^1(M)} \oplus \overline{*d\Lambda^1(M)}, \\
 \Lambda^3(M) &= *\text{Ker}(\Delta_1) \oplus \overline{*d\Lambda^0(M)} \oplus *(\Lambda^1(M)/\text{Ker}(d)), \\
 \Lambda^4(M) &= *\text{Ker}(\Delta_0) \oplus *(\Lambda^0(M)/\text{Ker}(d)).
 \end{aligned}$$

Thus for the zero-in-the-spectrum question, it is enough to consider $\text{Ker}(\Delta_0)$, $\text{Ker}(\Delta_1)$, $\sigma(\Delta_0 \text{ on } \Lambda^0/\text{Ker}(d))$, $\sigma(\Delta_1 \text{ on } \Lambda^1/\text{Ker}(d))$ and $\text{Ker}(\Delta_2)$.

Let Γ be a finitely-presented group. Recall that Γ is the fundamental group of some closed 4-manifold. To see this, take a finite presentation of Γ . Embed the resulting presentation complex in \mathbf{R}^5 and take the boundary of a regular neighborhood to get the manifold.

Now consider the Euler characteristics of all closed 4-manifolds X with fundamental group Γ . Given X , we have $\chi(X\#\mathbf{CP}^2) = \chi(X) + 1$. Thus it is easy to make the Euler characteristic big. However, it is not so easy to make it small. From what has been said,

$$\begin{aligned}
 &\{\chi(X): X \text{ is a closed connected oriented 4-manifold with} \\
 (5.8) \quad &\pi_1(X) = \Gamma\} = \{n \in \mathbf{Z} : n \geq q(\Gamma)\}
 \end{aligned}$$

for some $q(\Gamma)$. *A priori* $q(\Gamma) \in \mathbf{Z} \cup \{-\infty\}$, but in fact $q(\Gamma) \in \mathbf{Z}$ [17, Theorem 1]. (This also follows from (5.9) below.) It is a basic problem in 4-manifold topology to get good estimates of $q(\Gamma)$.

Suppose that $\pi_1(X) = \Gamma$. From Properties 4, 7 and 8 above,

$$(5.9) \quad \chi(X) = 2b_0^{(2)}(\Gamma) - 2b_1^{(2)}(\Gamma) + b_2^{(2)}(X).$$

In particular, if $b_1^{(2)}(\Gamma) = 0$ then $\chi(X) \geq 0$ and so $q(\Gamma) \geq 0$. This is the case, for example, when Γ is big or when Γ is amenable [5].
