A THEOREM OF INGHAM IMPLYING THAT DIRICHLET'S L-FUNCTIONS HAVE NO ZEROS WITH REAL PART ONE

by Paul T. BATEMAN

§ 1. INTRODUCTION

Using Landau's lemma on Dirichlet series with non-negative coefficients, A. E. Ingham in [1] proved the following theorem.

INGHAM'S THEOREM. Let

$$g(s) = g(s, \epsilon) = \prod_{p} \left(1 - \frac{\epsilon(p)}{p^s}\right)^{-1} = \sum_{n=1}^{\infty} \frac{\epsilon(n)}{n^s}$$
 (Re $s > 1$),

where the product is extended over all prime numbers p and ϵ is a bounded completely multiplicative arithmetic function. Suppose that g can be analytically continued into some domain containing the closed interval $\left[\frac{1}{2},1\right]$ of the real axis. Then

$$g(1) \neq 0$$
.

We recall that an arithmetic function ϵ is said to be completely multiplicative if $\epsilon(mn) = \epsilon(m) \, \epsilon(n)$ for all positive integers m and n. Since a completely multiplicative arithmetic function ϵ is determined by the values $\epsilon(p)$ for primes p, it is immediate that ϵ is bounded if and only if $|\epsilon(p)| \leq 1$ for all primes p. Actually Ingham assumed that $|\epsilon(p)|$ is either 0 or 1 for any prime p, but his proof can easily be modified to require only that $|\epsilon(p)| \leq 1$. (Cf. [6]).

The most interesting application of Ingham's theorem is that obtained by taking $\epsilon(n)=\chi(n)n^{-i\alpha}$, where χ is a residue character modulo k and α is a real number which is different from zero if χ is the principal character. Then

 $g(s) = L(s + i\alpha, \chi)$ and the theorem gives the assertion $L(1 + i\alpha, \chi) \neq 0$. The main interest in Ingham's theorem is its breadth of applicability. In contrast the familiar use of a trigonometric inequality does not cover the case in which $\alpha = 0$ and χ is a real non-principal character; that case is the very one to which Landau's lemma applies most easily (cf. §2 of [3]).

Ingham proved the theorem by establishing and using the identity

(*)
$$\zeta(s) g(s,\epsilon) g(s,\eta) g(s,\epsilon\eta) = g(2s,\epsilon\eta) \sum_{n=1}^{\infty} E(n) H(n) n^{-s},$$

where ζ denotes the Riemann zeta function, η is another completely multiplicative arithmetic function, $\epsilon\eta$ is the pointwise product of ϵ and η , and

$$E(n) = \sum_{d|n} \epsilon(d), \quad H(n) = \sum_{d|n} \eta(d).$$

This is a generalization of a result of Ramanujan for the case $\epsilon(n) = n^a$, $\eta(n) = n^b$, where a and b are fixed complex numbers.

While the identity (*) is of some interest in itself, we show that for the purpose of proving Ingham's theorem there is no reason to make the detour needed to prove (*). Of course we still require Landau's lemma, which we state in the following form.

LANDAU'S LEMMA. Suppose β and γ are real numbers with $\beta < \gamma$. Suppose that $c_n \geq 0$ for n = 1, 2, 3, ... and that the series $\sum c_n n^{-s}$ converges for $\text{Re } s > \gamma$. Put

$$f(s) = \sum_{n=1}^{\infty} c_n n^{-s} \qquad (\text{Re } s > \gamma).$$

If f can be analytically continued into some domain containing the closed interval $[\beta, \gamma]$ of the real axis, then the series $\sum c_n n^{-\beta}$ converges.

For a proof of Landau's lemma see [5], [4], or §2 of [2].

The proof of Ingham's theorem which we give here uses an argument similar to that used in [4] and [5], except that the argument in those two papers was phrased in such a way as to require analytic continuation into a domain containing the interval [0,1] of the real axis instead of the interval $\left[\frac{1}{2},1\right]$. The interval $\left[\frac{1}{2},1\right]$ could not be replaced in the hypothesis of Ingham's theorem by a shorter interval, i.e., one of the form $[\theta,1]$, where $\theta>\frac{1}{2}$; this is shown by the example in which ϵ is the Liouville function λ and $g(s)=\zeta(2s)/\zeta(s)=\sum \lambda(n)\,n^{-s}$.

§2. Proof of Ingham's Theorem

Suppose that g(1) = 0. We show that this assumption leads to a contradiction. We consider the function

$$F(s) = \zeta(s)^2 g(s) g^*(s)$$
 (Re $s > 1$),

where $g^*(s) = g(s, \overline{\epsilon})$ and $\overline{\epsilon}$ is the arithmetic function which is the complex conjugate of ϵ . Clearly $g^*(1) = \overline{g(1)} = 0$. By hypothesis g is regular along the stretch $\left[\frac{1}{2}, 1\right]$ of the real axis and so therefore is g^* , since $g^*(s) = \overline{g(\overline{s})}$. Hence F is regular on $\left[\frac{1}{2}, 1\right]$, since the double pole of ζ^2 at s = 1 is canceled by the zeros of g and g^* there.

Using the identity

$$(1-z)^{-1} = \exp\left(\sum_{k=1}^{\infty} z^k / k\right)$$
 $(|z| < 1)$

we obtain (for Re s > 1)

$$F(s) = \prod_{p} \left(1 - \frac{1}{p^s} \right)^{-2} \left(1 - \frac{\epsilon(p)}{p^s} \right)^{-1} \left(1 - \frac{\overline{\epsilon}(p)}{p^s} \right)^{-1}$$

$$= \prod_{p} \exp\left(\sum_{k=1}^{\infty} \frac{2 + \epsilon(p)^k + \overline{\epsilon}(p)^k}{kp^{ks}} \right)$$

$$= \prod_{p} \left\{ 1 + \left(\sum_{k=1}^{\infty} \frac{2 + \epsilon(p)^k + \overline{\epsilon}(p)^k}{kp^{ks}} \right) + \frac{1}{2} \left(\sum_{k=1}^{\infty} \frac{2 + \epsilon(p)^k + \overline{\epsilon}(p)^k}{kp^{ks}} \right)^2 + \cdots \right\}.$$

Thus F has a Dirichlet series expansion

$$F(s) = \sum_{n=1}^{\infty} a(n) n^{-s}$$
 (Re $s > 1$).

Furthermore, since

$$2 + \epsilon(p)^k + \overline{\epsilon}(p)^k = 2 + 2 \operatorname{Re}\{\epsilon(p)^k\} \ge 0,$$

we have $a(n) \ge 0$ for all n.

At this point we deviate from the approach used in [4] and [5] by noting that $a(p^2) \ge 1$ for each prime p. For, since

$$F(s) = \prod_{p} \left(1 + \frac{2}{p^s} + \frac{3}{p^{2s}} + \cdots \right) \left(1 + \frac{\epsilon(p)}{p^s} + \frac{\epsilon(p)^2}{p^{2s}} + \cdots \right) \left(1 + \frac{\overline{\epsilon}(p)}{p^s} + \frac{\overline{\epsilon}(p)^2}{p^{2s}} + \cdots \right),$$

we find that

$$a(p^{2}) = 3 + 2\epsilon(p) + 2\overline{\epsilon}(p) + \epsilon(p)^{2} + \epsilon(p)\overline{\epsilon}(p) + \overline{\epsilon}(p)^{2}$$
$$= 2 - \epsilon(p)\overline{\epsilon}(p) + \{1 + \epsilon(p) + \overline{\epsilon}(p)\}^{2}$$
$$\geq 2 - |\epsilon(p)|^{2} \geq 1.$$

Thus

$$\sum_{n=1}^{\infty} \frac{a(n)}{n^{1/2}} \ge \sum_{p} \frac{a(p^2)}{p} \ge \sum_{p} \frac{1}{p}.$$

In view of the divergence of $\sum p^{-1}$, it follows that $\sum a(n) n^{-1/2}$ diverges. On the other hand, applying Landau's lemma with $c_n = a(n)$, $\beta = \frac{1}{2}$, $\gamma = 1$, we find that $\sum a(n) n^{-1/2}$ converges. This contradiction shows that the assumption g(1) = 0 is untenable and so the proof is complete.
