written, it is assumed to be the integers. There are two forms of duality available which we will use. First, Poincaré duality asserts that cap product with the fundamental class  $[X] \in H_4(X)$  gives an isomorphism  $D : H^2(X) \to H_2(X)$ . There is a similar isomorphism when we use  $\mathbb{Z}_2$  coefficients which we will also denote by D. For coefficient group  $\mathbb{Z}_2$  there is an isomorphism  $H: H^2(X; \mathbb{Z}_2) \to \operatorname{Hom}_{\mathbb{Z}_2}(H_2(X; \mathbb{Z}_2), \mathbb{Z}_2)$  with image the dual space of the vector space  $H_2(X; \mathbb{Z}_2)$  over the field  $\mathbb{Z}_2$ . A basis  $b_1, \ldots, b_n$  of a finite dimensional vector space V determines an isomorphism between V and its dual  $V^*$  by sending  $b_i$  to the homomorphism  $B_i$  which sends  $b_i$  to 1 and  $b_j$  to 0 for  $j \neq i$ . The elements  $B_i$  and  $b_i$  are said to be *Hom duals*. This isomorphism depends on a choice of basis. However, if we are given any elements  $b \in V$ ,  $B \in V^*$ , with B(b) = 1, then we can always extend  $b = b_1$ to a basis of V so that b is the Hom dual of B — just extend b to any basis and then subtract off appropriate multiples of b to get B to evaluate 0 on the other basis elements. The composition of the isomorphism H and the isomorphism determined by the basis gives an isomorphism

$$\overline{H}: H^2(X; \mathbf{Z}_2) \simeq \operatorname{Hom}_{\mathbf{Z}_2}(H_2(X; \mathbf{Z}_2), \mathbf{Z}_2) \simeq H_2(X; \mathbf{Z}_2)$$

which will be called *Hom duality*. We will call  $x \in H_2(X; \mathbb{Z}_2)$  a *Hom dual* of  $h \in H^2(X; \mathbb{Z}_2)$  if H(h)(x) = 1 since we can always choose a basis of  $H_2(X; \mathbb{Z}_2)$  so that  $\overline{H}(h) = x$ .

We next explore briefly the notions of an even intersection form, spin structure, and spin<sup>c</sup> structure for a compact, oriented smooth 4-manifold X. For more details see [B, p. 366–378], [K, p. 20–26, 33–37], [A, p. 95–101], [M, p. 20–25]. The intersection form  $H_2(X) \times H_2(X) \rightarrow \mathbb{Z}$  is defined by using the intersection product  $a \cdot b$  of two homology classes. If the homology classes are represented by smoothly embedded oriented surfaces A, B (i.e. the inclusion maps induce  $(i_A)_*[A] = a, (i_B)_*[B] = b$ , then  $a \cdot b$  may be computed by perturbing A, B up to isotopy to be transversely embedded and summing up the intersections with signs  $\pm 1$  according to whether the orientation framing of A followed by the orientation framing of B agrees or disagrees with the orientation framing of X [B, p. 375]. It is always the case that a 2-dimensional homology class in an oriented 4-manifold may be represented by an embedded surface [K, p. 20]. The product  $a \cdot b$  may also be computed using Poincaré duality as  $a \cdot b = \alpha \cup \beta[X] = \alpha(b)$ , where  $D\alpha = a, D\beta = b$ . There are similar formulas with  $Z_2$  coefficients. A two dimensional  $Z_2$  homology class is not always represented by an embedded oriented surface, but it always may be represented by an embedded nonorientable surface [G, p. 165-166], and there is a similar interpretation of the intersection form in terms of counting geometric transverse intersections. The map  $H_2(X) \rightarrow H_2(X; \mathbb{Z}_2)$  is surjective exactly when every  $\mathbb{Z}_2$  homology class can be represented by an orientable surface.

The universal coefficient sequences with integral and  $\mathbb{Z}_2$  coefficients lead to the following diagram.

The homomorphisms  $h_1$  and  $h_2$  are related to the intersection form:

$$h_1(\alpha)(b) = a \cdot b, \quad h_2(\alpha)(b) = a \cdot b \mod 2$$

where  $D(\alpha) = a$  with either **Z** or **Z**<sub>2</sub> coefficients. The homomorphisms  $\rho_i$ come from reduction mod 2. The intersection form is called *even* if  $x \cdot x$ is an even number for all  $x \in H_2(X)$ . An integral class  $a \in H_2(X)$  so that  $a \cdot x = x \cdot x \mod 2$  for all x is called *characteristic* for the intersection form. a is characteristic if the homomorphism  $S(x) = x \cdot x \mod 2$  is the image of a under the homomorphism  $k: H_2(X; \mathbf{Z}) \longrightarrow \operatorname{Hom}(H_2(X), \mathbf{Z}_2)$  where  $k(a)(x) = a \cdot x \mod 2$ . If a is a characteristic class, and  $\alpha$  is its Poincaré dual, then  $h_1(\alpha)(x) = a \cdot x = x \cdot x \mod 2$ . Thus a is characteristic iff its Poincaré dual  $\alpha$  satisfies  $h_2\rho_1(\alpha) = \rho_2h_1(\alpha) = S$ . Since the form is even iff S = 0, this means that the form is even iff for a characteristic,  $D\alpha = a$ , then  $h_2(\rho_1(\alpha)) = 0$ .

The existence of characteristic classes uses the nondegeneracy of the intersection form and Poincaré duality with  $\mathbb{Z}_2$  coefficients. The intersection pairing  $H_2(X; \mathbb{Z}) \times H_2(X; \mathbb{Z}) \longrightarrow \mathbb{Z}$  factors through  $\Gamma \times \Gamma \longrightarrow \mathbb{Z}$  where  $\Gamma = H_2(X; \mathbb{Z})/\text{Tors}$ , and when we reduce mod 2, through  $\Gamma_2 \times \Gamma_2 \longrightarrow \mathbb{Z}_2$  where  $\Gamma_2 = \Gamma \otimes \mathbb{Z}_2$ . The existence follows from  $\Gamma \longrightarrow \Gamma_2$  being surjective and  $\Gamma_2 \longrightarrow \text{Hom}(\Gamma_2, \mathbb{Z}_2)$  being an isomorphism. For this last isomorphism, note both sides are  $\mathbb{Z}_2$ -vector spaces and have dimension equal to rank  $H_2(X; \mathbb{Z})$ . The isomorphism is established once the map is seen to be injective. This follows from the fact that the intersection form is nondegenerate due to Poincaré duality: for each  $v, \exists w$  with  $w \cdot v = 1$ ; in fact,  $w = D\psi$  where  $\psi$  is the Hom dual of v:

$$w \cdot v = D\psi \cdot v = H(\psi)(v) = 1.$$

The second Stiefel-Whitney class  $w_2(X) \in H^2(X; \mathbb{Z}_2)$  belongs to a family of characteristic classes. A good reference for properties of the Stiefel-Whitney classes and characteristic classes in general is [MS]. For our discussion here we need to know three of its properties. First, it is related to the characteristic classes discussed above in that its Poincaré dual  $D(w_2(X))$  satisfies the characteristic property for the  $\mathbb{Z}_2$  intersection form:

$$H(w_2(X))(z) = D(w_2(X)) \cdot z = z \cdot z$$

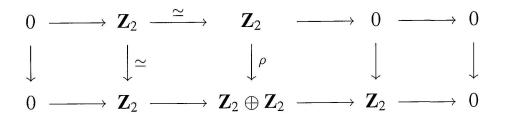

for all  $z \in H_2(X; \mathbb{Z}_2)$ . When we restrict to the image of integral classes, we get the statement that  $h_2(w_2(X))(x) = x \cdot x \mod 2$ . This means that if  $D(\alpha_1)$  is an integral characteristic class, then  $h_2(w_2 - \rho_1(\alpha_1)) = 0$ . The second property that  $w_2(X)$  satisfies is that an oriented manifold X has a spin structure iff  $w_2(X) = 0$ . A spin structure on X is a lifting of the structure group of the tangent bundle of X from SO(4) to its universal (double)cover spin(4). The third property which  $w_2(X)$  possesses relates to  $spin^c$  structures. The group  $spin^c(4)$  is the double cover  $spin(4) \times S^1/\pm 1$  of  $SO(4) \times S^1$  induced from the double cover on each factor. A  $spin^c$  structure on X consists of a lifting of the structure group of the product of the tangent bundle of X and a chosen line bundle L over X from  $SO(4) \times S^1$  to  $spin^c(4)$ . The 4-manifold X has a  $spin^c$  structure exactly when the second Stiefel-Whitney class  $w_2(X) = \rho_1(\alpha)$ for some integral class  $\alpha$  ([HH, p. 169], [M, p. 25]).

We now give the argument why  $w_2(X)$  always lifts to an integral class from the excellent expository account of Seiberg-Witten invariants by S. Akbulut [A, p. 95]. We saw above that the existence of an integral characteristic class means there is an integral class  $\alpha_1$  so that  $h_2(w_2(X) - \rho_1(\alpha_1)) = 0$ . Hence  $w_2 - \rho_1(\alpha_1)$  comes from  $\text{Ext}(H_1(X), \mathbb{Z}_2)$ . But the map  $\text{Ext}(H_1(X), \mathbb{Z}) \longrightarrow \text{Ext}(H_1(X), \mathbb{Z}_2)$  is surjective since the first group gives the torsion subgroup of  $H_1(X)$  and the latter the 2-torsion subgroup. Hence  $\exists \alpha_2 \in \text{Ext}(H_1(X), \mathbb{Z}) \hookrightarrow H^2(X; \mathbb{Z})$  with  $\rho_1(\alpha_2) = w_2 - \rho_1(\alpha_1)$ . This implies  $w_2 = \rho_1(\alpha_1 + \alpha_2)$  is the image of an integral cohomology class. Note that this also means that the Poincaré dual  $D(w_2)$  is the image of an integral homology class.

With this background, we return now to our initial example M. To see that  $w_2(M) \neq 0$ , Habegger [H] notes that if  $\mathbb{RP}^2 = \{[(x, x)]\}$  is the image of the diagonal  $\triangle$  in  $S^2 \times S^2$  under the quotient, then  $[\triangle] \cdot [\triangle] = 2$  in  $S^2 \times S^2$ leads to  $[\mathbb{RP}^2] \cdot [\mathbb{RP}^2] = 1$  in M. If  $[\mathbb{RP}^2] = D\gamma$ , where  $\gamma \in H^2(M; \mathbb{Z}_2)$ , then we have  $(\gamma \cup \gamma)[M] = [\mathbb{RP}^2] \cdot [\mathbb{RP}^2] = 1$ . Thus  $w_2(M) \cup \gamma = \gamma \cup \gamma \neq 0$ , which implies  $w_2(M) \neq 0$  and thus M is not spin.

Next note  $\pi_1(M) = \mathbb{Z}_2 = H_1(M)$  since M is double covered by  $S^2 \times S^2$ . Using this and the computation of Euler characteristic as  $\chi(M) = \chi(S^2 \times S^2)/2 = 2$ , Habegger shows rank  $H_2(M) = 0$ . Evenness of the

intersection form follows. The universal coefficient sequences for M are:

Consider the homology class  $Dw_2$ . We claim that it is represented by the embedded sphere which is the image under the quotient of  $S^2 \times p$  or  $p \times S^2$  in  $S^2 \times S^2$ . Here p is a chosen point in  $S^2$ , say (1,0,0). To see this, note that  $(S^2 \times p) \cap \Delta = (p,p)$  and the intersection is transverse. This gives us  $[S^2 \times p]_2 \cdot [\mathbf{RP}^2] = 1$  in M, and  $[S^2 \times p]_2$  is therefore a nonzero class in  $H_2(M; \mathbf{Z}_2)$  — the subscript 2 indicates that here we are viewing  $[S^2 \times p]$  as a  $\mathbf{Z}_2$  homology class rather than an integral class. This implies  $[S^2 \times p]$  must be nonzero in  $H_2(M) \simeq \mathbf{Z}_2$ . Its Poincaré dual in  $H^2(M) \simeq \mathbf{Z}_2$  must therefore be the unique nonzero class which reduces mod 2 to  $w_2(M)$ . This is reflected in our commutative diagram. Evenness is reflected through the upper right term being zero, and the image of  $w_2$  to the Hom term being zero. Exactness implies  $w_2 \in \mathbf{Z}_2 \oplus \mathbf{Z}_2$  must come from the Ext term. Note that under the isomorphism  $\mathbf{Z}_2 \oplus \mathbf{Z}_2 \simeq H^2(M; \mathbf{Z}_2) \simeq \text{Hom}_{\mathbf{Z}_2}(H_2(M; \mathbf{Z}_2), \mathbf{Z}_2), w_2$  maps to a nonzero homomorphism which evaluates zero on  $[S^2 \times p]_2$  and one on  $[\mathbf{RP}^2]$ .

What is true here is that the class  $[\mathbf{RP}^2]$  in  $H_2(M; \mathbf{Z}_2)$  does not come from an integral class. The evaluation of  $w_2$  on  $[\mathbf{RP}^2]$  and  $[S^2 \times p]_2$  distinguishes these classes. Thus, these two surfaces generate  $H_2(M; \mathbf{Z}_2) = \mathbf{Z}_2 \oplus \mathbf{Z}_2$  and the intersection form with respect to this basis is just  $\begin{pmatrix} 1 & 1 \\ 1 & 0 \end{pmatrix}$ . We also note that  $[\mathbf{RP}^2]$  cannot be represented by an oriented surface N. If it were, [N] would represent an element of  $H_2(M)$ , and as we have seen,  $[\mathbf{RP}^2]$  is not in the image of the homomorphism  $H_2(M) \longrightarrow H_2(M; \mathbf{Z}_2)$  since the form is even.

How typical is this example ? First, if X has an even intersection form and  $w_2(X) \neq 0$ , then there must be a class  $a \in H_2(X; \mathbb{Z}_2)$  with  $a \cdot a \neq 0$  detecting  $w_2(X) \neq 0$  so that a does not come from an integral class. This class a can be taken as a Hom dual of  $w_2(X)$ , not the Poincaré dual. In our example,  $[\mathbb{RP}^2]$  is the Hom dual to  $w_2(M)$  (using the basis  $[S^2 \times p]_2, \mathbb{RP}^2$  to form the duality) since  $H(w_2(M))([\mathbb{RP}^2]) = 1$  and  $H(w_2(M))([S^2 \times p]_2) = 0$ . Of course, no such example can have  $H_2(X) \longrightarrow H_2(X; \mathbb{Z}_2)$  surjective, which implies X is not simply connected. Secondly,  $H_2(X; \mathbb{Z}_2)$  is always represented by embedded surfaces, orientable or nonorientable. All classes in the image
