starts at the tip of  $D_{cc}$  (i.e. at the same point as  $\Gamma_i \cap D_c$  and  $\varphi(\Gamma_i) \cap D_c$ ), and falls into one of the punctures in the right half of  $D_{cc}$ . By construction,  $\gamma_{\alpha} \cap D_{cc}$  is reduced with respect to  $\sigma$ , since both are geodesics, and the first component of  $\varphi(\gamma_{\alpha}) \cap D_{cc}$  is even disjoint from  $\sigma$ . In the universal cover we now have that the lifting  $\widetilde{\sigma}$  of  $\sigma$  ends on the circle at infinity, thus separating  $\widetilde{D}_{cc}$  into two components, the left one containing the lift of  $\varphi(\gamma_{\alpha}) \cap D_{cc}$ , and the right one the lift of  $\gamma_{\alpha} \cap D_{cc}$ . Thus lifts of these two curves, not being allowed to intersect any component of  $\partial D_{cc}$  and  $\partial D_{cc}$  more than once, go on to hit different points of  $\partial D_n$ , with  $\widetilde{\varphi}(\widetilde{\gamma}_{\alpha})$  staying more to the left than  $\widetilde{\gamma}_{\alpha}$ . This completes the proof of the third case, and thus of Theorem 6.1.

*Proof of Theorem 3.3* (b). If  $\gamma_{\alpha}$  fills  $D_n$ , then  $C(\gamma_{\alpha})$  is a total curve diagram, and thus induces a *total* ordering of  $B_n$ . By Corollary 6.2, the ordering of  $B_n$  associated to the point  $\alpha \in (0, \pi)$  agrees with this ordering.

*Proof of Theorem 3.4* (b). For any two geodesics  $\gamma_{\alpha}$  and  $\gamma_{\beta}$  of finite type one can work out their associated curve diagrams  $C(\gamma_{\alpha})$  and  $C(\gamma_{\beta})$ . By Corollary 6.2 it is sufficient to decide whether or not the orderings associated to the two curve diagrams coincide, which can be done by Theorem 5.2.

Proof of Theorem 3.5. It only remains to be proved that  $N_n = M_n$  (where  $M_n$  is given in Proposition 5.3), i.e. that every curve diagram is realized up to loose isotopy as  $C(\gamma_\alpha)$  for some geodesic  $\gamma_\alpha$ ,  $\alpha \in (0, \pi)$ . This is left as an exercise to the reader.

# 7. Orderings associated to geodesics of infinite type

In this section we prove the results concerning orderings of infinite type, and explain the essential differences between finite and infinite type orderings.

We start by describing in more detail than in Section 3 the structure of geodesics of infinite type. We define the curve diagram  $C(\gamma_{\alpha})$  associated to a geodesic of infinite type by precisely the same inductive construction procedure as in the finite type case. Except for a finite initial segment, the last arc  $\Gamma_j$  will lie in some path component  $D_c$  of  $D_n \backslash N\Gamma_{0 \cup \cdots \cup j-1}$ , the only difference with the finite type case is that  $\Gamma_j$  goes on for ever, without falling into a puncture and without spiralling. The closure of  $\Gamma_j$  inside this critical component  $D_c$  is a geodesic lamination; the lamination has no closed leaves, for such a leaf would have to be the limit of an infinite spiral of  $\Gamma_j$  (see [17, Appendix]). All self-intersections of the geodesic  $\gamma_{\alpha}$  occur inside the finite

initial segment up to the entry into the punctured disk  $D_c$ ; in particular, there are only finitely many self-intersections.

Proof of Theorem 3.3 (c). We are studying the set

$$\mathcal{I} := \{ \alpha \in (0, \pi) \mid \gamma_{\alpha} \text{ is of infinite type} \}.$$

The proof uses standard results from the theory of geodesic laminations and the Nielsen-Thurston classification of surface automorphisms [5, 17].

That  $\mathcal{I}$  has uncountably many elements follows from the fact that there are uncountably many geodesic laminations of  $D_n$ , only countably many of which fall into infinite spirals. A more practical way of seeing this is to choose arbitrarily a fundamental domain of  $D_n$  by fixing n geodesic arcs, e.g. as shown in Figure 1. Thus the fundamental domain is a 2n+1-gon with one boundary edge corresponding to  $\partial D_n$  and n pairs of boundary edges which are identified in  $D_n$ . A segment of the geodesic between any two successive intersections with the boundary of the fundamental domain consists of an embedded arc connecting different edges of the 2n+1-gon. Hence constructing a geodesic of infinite type amounts to choosing an infinite "cutting sequence" of the geodesic with the boundary arcs of the fundamental domain. Often the choice will be forced upon us by the requirement that the geodesic be embedded, but there will be an infinite number of times when we have a genuine choice. Thus the set of all possible sequences of choices is uncountable.

The cutting sequence approach also makes it clear why any neighbourhood of an  $\alpha \in \mathcal{I}$  in  $(0,\pi)$  contains points  $\alpha' \neq \alpha$  of  $\mathcal{I}$  as well as  $\beta \in (0,\pi) \setminus \mathcal{I}$ . Given  $\alpha \in (0,\pi)$  and  $\epsilon > 0$ , there exists an  $N_{\epsilon} \in \mathbb{N}$  such that all geodesics  $\gamma_{\delta}$  whose cutting sequences agree with the one of  $\gamma_{\alpha}$  for at least  $N_{\epsilon}$  terms satisfy  $|\alpha - \delta| < \epsilon$ . Now for any  $\alpha \in \mathcal{I}$  and  $\epsilon > 0$  we can find a geodesic  $\gamma_{\alpha'}$  of infinite type whose cutting sequence diverges from the one of  $\gamma_{\alpha}$  only after the  $N_{\epsilon}$  th term. On the other hand, we can construct a geodesic  $\gamma_{\beta}$  with  $|\alpha - \beta| < \epsilon$  which fills  $D_n$  in finite time: just choose it to have a cutting sequence which agrees with the one of  $\gamma_{\alpha}$  for  $N_{\epsilon}$  terms, and to then career off along some path which decomposes  $D_n$  into disks and once-punctured disks.

Finally, the last part of Theorem 3.3(c) holds because each of the countably many elements of  $B_n$  fixes only a countable number of points  $\alpha \in (0, \pi)$  with the property that  $\gamma_{\alpha}$  fills  $D_n$ . In order to see this, we note that for *irreducible* elements of  $B_n$  Theorem 5.5 of [5] states that there is only a finite number of fixed points on the circle at infinity. If an element  $\varphi$  of  $B_n$  is *reducible*, then

we leave it to the reader to check that the result follows from the following facts:

- (1) One can find a maximal invariant system C of disjoint properly embedded arcs and circles in  $D_n$ .
- (2) If  $\varphi$  acts nontrivially on a component of  $D_n \setminus C$  which is cut in a nontrivial way by a *finite* segment of  $\gamma_\alpha$ , then it acts nontrivially on  $\gamma_\alpha$  (for if it didn't then the collection C would not be maximal).
- (3) A geodesic  $\gamma_{\alpha}$  that fills  $D_n$  has to enter every component of  $D_n \setminus C$  at least once, and  $\varphi$  acts nontrivially either on the first or, failing that, on the second component of  $\gamma_{\alpha} \cap (D_n \setminus C)$  (because it cannot act trivially on two adjacent components of  $D_n \setminus C$ ).
- (4) There is a countable infinity of isotopy classes of embedded arcs from the basepoint of  $D_n$  to C.

We recall from the beginning of the section that to every geodesic  $\gamma_{\alpha}$  of infinite type we have associated a "critical disk"  $D_c$  which contains most of the last arc of  $C(\gamma_{\alpha})$ . The fundamental property of geodesics of infinite type which we shall use several times is the following.

LEMMA 7.1. For any geodesic of infinite type  $\gamma_{\alpha}$  and for any  $\epsilon > 0$  there exists a geodesic  $\gamma_{\alpha^+}$  with  $\alpha^+ \in (\alpha, \alpha + \epsilon)$  such that  $\gamma_{\alpha^+}$  falls into a puncture and has no self-intersections inside  $D_c$ .

*Proof.* It suffices to prove the lemma in the special case  $D_c = D_n$ , i.e. when the geodesic  $\gamma_{\alpha}$  is embedded. We suppose, for a contradiction, that there exists an  $\epsilon > 0$  such that no  $\gamma_{\beta}$  with  $\beta \in (\alpha, \alpha + \epsilon)$  is embedded and falls into a puncture. Our aim is to reach the contradiction that  $\gamma_{\alpha}$  ends in an infinite spiral.

We continue to use the notions concerning cutting sequences introduced above: we choose arbitrarily a fundamental domain, and we shall denote by  $\gamma_{\alpha}^k$  the initial segment of  $\gamma_{\alpha}$  up to its  $k^{\text{th}}$  intersection with the boundary of the fundamental domain. We recall that, given  $\gamma_{\alpha}$  and  $\epsilon > 0$ , we can find an  $N = N_{\epsilon} \in \mathbb{N}$  such that any geodesic  $\gamma_{\beta}$  with  $\gamma_{\beta}^N = \gamma_{\alpha}^N$  satisfies  $|\alpha - \beta| < \epsilon$ . We now consider the arc  $\gamma_{\alpha}^{N+1}$ : it ends on some boundary arc of the fundamental domain which we denote a. The orientation of  $\gamma_{\alpha}$  gives rise to a notion of the part of a "to the left" and "to the right of" the end point of  $\gamma_{\alpha}^{N+1}$ . The arc  $\gamma_{\alpha}^{N+1}$  has an intersection with the interior of the "left" part of a, for if this were not the case we could obtain an embedded arc  $\gamma_{\beta}$ 

with  $\beta \in (\alpha, \alpha + \epsilon)$  by adjoining to the end point of  $\gamma_{\alpha}^{N}$  an arc falling into the puncture at the left end of a; this would contradict the hypothesis. Thus it makes sense to define  $\Gamma \subseteq D_n$  to be the union of  $\gamma_{\alpha}^{N+1}$  and a segment of a from the end point of  $\gamma_{\alpha}^{N+1}$  to the left, up to the next intersection with  $\gamma_{\alpha}^{N+1}$  (see Figure 10).

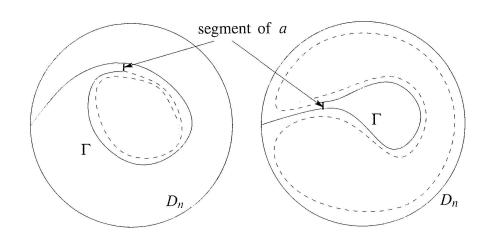

FIGURE 10

The two possible shapes of  $\Gamma$ , and (dashed) the resulting geodesic  $\gamma_{\alpha}$ 

We now observe that  $D_n \setminus \Gamma$  has two path components, each containing at least one puncture; moreover,  $\gamma_{\alpha}$  cannot intersect any geodesic arc connecting two punctures in the same component, because the first time it did we could drop it into the puncture at the left end of the arc and obtain a contradiction as before. It follows that  $\gamma_{\alpha}$  has to spiral along the boundary of one of the components of  $D_n \setminus \Gamma$ .  $\square$ 

PROPOSITION 7.2. All orderings, even partial ones, arising from geodesics  $\gamma_{\alpha}$  of infinite type are non-discrete.

*Proof.* We shall prove the following stronger statement: for any  $\epsilon > 0$  there exists an element  $\varphi \in \mathcal{MCG}(D_n) = B_n$  such that  $\varphi(\alpha) \in (\alpha, \alpha + \epsilon)$ .

We choose  $\alpha^+$  as in the previous lemma. We consider the boundary curve  $\tau$  of a regular neighbourhood of  $\partial D_c \cup \gamma_{\alpha^+}$  in  $D_c$ . This curve  $\tau$  is disjoint from  $\gamma_{\alpha^+}$ , while any curve isotopic to  $\tau$  necessarily intersects  $\gamma_{\alpha}$ . Thus for the positive Dehn twist T along  $\tau$  we have that  $T(\alpha) > \alpha$  (by Proposition 2.4), and that  $T(\alpha^+) = \alpha^+$ . It follows that  $T(\alpha) \in (\alpha, \alpha^+) \subseteq (\alpha, \alpha + \epsilon)$ .

*Proof of Theorem 3.4* (a). Given a geodesic  $\gamma_{\alpha}$  of finite, and a geodesic  $\gamma_{\beta}$  of infinite type, our aim is to prove that  $\gamma_{\alpha}$  and  $\gamma_{\beta}$  cannot induce the same orderings of  $B_n$ .

As seen in Corollary 6.2, orderings arising from geodesics which fill the surface in finite time are the same as orderings arising from total curve diagrams, which are discrete by Lemma 4.5. By contrast, we have from Proposition 7.2 that infinite type orderings are not discrete. This proves the theorem in the special case where the finite type geodesic fills the surface.

In the case where the finite type geodesic  $\gamma_{\alpha}$  does *not* fill the surface, we consider the subsurface  $D_{\alpha} := D_n \backslash NC(\gamma_{\alpha})$ , i.e. the maximal subsurface with geodesic boundary which is disjoint from  $\gamma_{\alpha}$ . We observe that  $D_{\alpha}$  is a disjoint union of disks, each containing at least two punctures. Any homeomorphism  $\varphi$  of  $D_n$  with support in  $D_{\alpha}$  has the property that  $\varphi(\alpha) = \alpha$ .

If  $D_{\alpha} \cap \gamma_{\beta} \neq \emptyset$  then there exists a homeomorphism  $\varphi$  with support in  $D_{\alpha}$  such that  $\varphi(\beta) \neq \beta$ , and it follows that the orderings induced by  $\alpha$  and  $\beta$  are different.

If, on the other hand,  $D_{\alpha} \cap \gamma_{\beta} = \emptyset$ , then we squash each component of  $D_{\alpha}$  to a puncture; the result is a disk with say m punctures, where m < n, which we denote  $D_m$ . We now consider the subgroup  $B_m^P$  of  $B_m = \mathcal{MCG}(D_m)$  of all mapping classes which fix those punctures of  $D_m$  that came from squashed components of  $D_{\alpha}$ . This is a finite index subgroup of  $B_m$ , and the orderings of  $B_n$  determined by  $\alpha$  and  $\beta$  induce quotient orderings on  $B_m^P$ . Another way to describe these quotient orderings is to repeat the Thurston-construction for the disk  $D_m$ : one can equip  $D_m$  with a hyperbolic metric, and then the geodesics  $\gamma_{\alpha}$  and  $\gamma_{\beta}$  project to quasigeodesics in  $D_m$ . These quasigeodesics determine points at infinity of the universal cover of  $D_m$ , and hence give rise to orderings of  $B_m$ .

The geodesic in  $D_m$  which is homotopic to the projection of  $\gamma_{\alpha}$  is again of finite type; the crucial observation now is that it fills  $D_m$ , so that the quotient ordering on  $B_m^P$  is discrete by Lemma 4.5. Similarly, a geodesic in  $D_m$  homotopic to the projection of  $\gamma_{\beta}$  is again of infinite type, hence induces, by Proposition 7.2 a non-discrete ordering on  $B_m$ , and thus also on the finite-index subgroup  $B_m^P$ . So the  $\alpha$ - and  $\beta$ -orderings on  $B_n$  give rise to different quotient orderings on  $B_m^P$ , and are therefore different.  $\square$ 

As seen above, every geodesic of infinite type gives rise to a curve diagram "of infinite type", which is like a curve diagram of finite type, except that the arc with maximal label is, up to isotopy, an infinite geodesic which does not fall into a puncture or a spiral. All but a finite initial segment of this arc lies in the "critical disk"  $D_c$ . There is an obvious generalisation of the notion of loose isotopy:

DEFINITION 7.3. Two curve diagrams of infinite type are *loosely isotopic* if they are related by (1) continuous deformation, i.e. a path in the space of all curve diagrams of infinite type; and (2) pulling loops around punctures tight.

This is exactly the same as in the finite type case, except that no "pulling loops around punctures tight"-procedure is defined for the last arc. We are now ready to state and prove the main classification theorem for orderings of  $B_n$  of infinite type.

THEOREM 7.4. Two geodesics  $\gamma_{\alpha}$  and  $\gamma_{\beta}$  of infinite type give rise to the same (possibly partial) ordering of  $B_n$  if and only if their associated curve diagrams  $C(\gamma_{\alpha})$  and  $C(\gamma_{\beta})$  are loosely isotopic.

*Proof.* By the results in the previous sections, it suffices to prove that two *embedded* geodesics  $\gamma_{\alpha}$  and  $\gamma_{\beta}$  of infinite type give rise to the same ordering of  $B_n$  if and only if  $\beta = \Delta^{2k}(\alpha)$  for some  $k \in \mathbb{Z}$ , i.e. if  $\gamma_{\alpha}$  and  $\gamma_{\beta}$  are related by a slide of the starting point around  $\partial D_n$ .

The implication " $\Leftarrow$ " is clear. Conversely, for the implication " $\Rightarrow$ ", we suppose that  $\gamma_{\alpha}$  and  $\gamma_{\beta}$  are not related by a slide of the starting point, and without loss of generality we say  $\alpha > \beta$ . Our aim is to construct a homeomorphism which is positive in the  $\alpha$ - and negative in the  $\beta$ -ordering, i.e. which sends  $\alpha$  "more to the left" and  $\beta$  "more to the right". Our argument will be a refinement of the proof of the implication " $\Rightarrow$ " of 5.2(a).

By Lemma 7.1 we can construct embedded geodesics  $\gamma_{\alpha^+}$  and  $\gamma_{\beta^+}$  which fall into punctures, and lie an arbitrarily small amount to the left of  $\gamma_{\alpha}$  respectively  $\gamma_{\beta}$ . We define the curves  $\tau_{\alpha^+}$  and  $\tau_{\beta^+}$  to be the geodesic representatives of the boundary curves of regular neighbourhoods in  $D_n$  of  $\partial D_n \cup \gamma_{\alpha^+}$  and  $\partial D_n \cup \gamma_{\beta^+}$  respectively. We denote by  $T_{\alpha^+}$  respectively  $T_{\beta^+}$  the positive Dehn twists along these curves. Our desired homeomorphism will be of the form  $T_{\alpha^+}^{-k} \circ T_{\beta^+}$ , with carefully chosen values of  $\alpha^+$  and  $\beta^+$ , and  $k \in \mathbb{N}$  very large.

We also define the two-sided infinite geodesic  $\tau_{\alpha}$  to be the geodesic which is disjoint from  $\gamma_{\alpha}$ , and isotopic to the boundary of a neighbourhood of  $\gamma_{\alpha} \cup \partial D_n$  in  $D_n$ . More formally, in the universal cover  $D_n^{\overline{z}}$  we consider two liftings of  $\gamma_{\alpha}$ , namely  $\widetilde{\gamma}_{\alpha}$  (which starts at the basepoint of  $D_n^{\overline{z}}$ ), and the lifting whose starting point also lies on  $\Pi$  and is obtained from the basepoint of  $\widetilde{D}_n$  by lifting the path once around  $\partial D_n$ . The end points of these geodesics

lie on the circle at infinity, and  $\tau_{\alpha}$  is just the projection of the geodesic connecting them.

Since  $\gamma_{\alpha}$  and  $\gamma_{\beta}$  are not loosely isotopic, we have that  $\gamma_{\beta}$  intersects  $\tau_{\alpha}$ . By choosing  $\beta^+$  sufficiently close to  $\beta$  we can now achieve that the initial segments of  $\gamma_{\beta}$  and  $\gamma_{\beta^+}$  up to their first point of intersection with  $\tau_{\alpha}$  are isotopic with end points sliding in  $\tau_{\alpha}$ . This gives our choice of  $\beta^+$ , and it remains to choose  $\alpha^+$  and k.

The crucial observation concerning  $\tau_{\alpha}$  is that it can be arbitrarily closely approximated by the curves  $\tau_{\alpha^+}$ , by choosing  $\alpha^+$  sufficiently close to  $\alpha$ . More precisely, in the universal cover  $D_n^{\bar{z}}$  we consider the preimages of  $\tau_{\alpha}$  and of  $\tau_{\alpha^+}$ . Each of them has infinitely many path components; we choose one distinguished component for each, namely the first ones that  $\gamma_{\beta}$  intersects. Our observation now is that as  $\alpha^+$  tends to  $\alpha$ , the end points of the distinguished component of the preimage of  $\tau_{\alpha^+}$  tend to the end points of the distinguished component of the preimage of  $\tau_{\alpha}$ .

We now turn to the choice of  $\alpha^+$ . By Proposition 2.4 we have that  $T_{\beta^+}(\alpha) > \alpha$ . By Lemma 7.1 we can now choose  $\alpha^+$  close to  $\alpha$  such that  $T_{\beta^+}(\alpha) > \alpha^+ > \alpha$ . By possibly pushing  $\alpha^+$  even closer to  $\alpha$ , we can in addition insist (by the observation concerning  $\tau_{\alpha}$  above) that the initial segments of  $\gamma_{\beta}$  and  $\gamma_{\beta^+}$  up to their first point of intersection with  $\tau_{\alpha^+}$  are also isotopic with end points sliding in  $\tau_{\alpha^+}$ . This gives our choice of  $\alpha^+$ .

We have arrived at the following setup: we have the three points  $\beta^+ = T_{\beta^+}(\beta^+) > T_{\beta^+}(\beta) > \beta$  in  $\partial D_n^{\bar{\gamma}} \backslash \Pi$ , and they all lie between the two end points  $\delta_l$  and  $\delta_r$  of the distinguished lifting of  $\tau_{\alpha^+}$  (here the indices l and r stand for "left" and "right", so  $\delta_l > \delta_r$ ). For any point  $\delta$  with  $\delta_l > \delta > \delta_r$  we consider the action of the positive Dehn twist  $T_{\alpha^+}$  on the geodesic  $\gamma_{\delta}$ . We observe that the limit  $\lim_{k\to\infty} T_{\alpha^+}^{-k}(\delta) = \delta_r$ . In particular for  $\delta:=\beta^+$  it follows that for sufficiently large k we have  $T_{\alpha^+}^{-k}(\beta^+) < \beta$ . This gives our choice of k.

To summarise, we have

$$T_{\alpha^+}^{-k} \circ T_{\beta^+}(\alpha) > T_{\alpha^+}^{-k}(\alpha^+) = \alpha^+ > \alpha$$

and

$$T_{\alpha^+}^{-k} \circ T_{\beta^+}(\beta) < T_{\alpha^+}^{-k} \circ T_{\beta^+}(\beta^+) = T_{\alpha^+}^{-k}(\beta^+) < \beta$$

i.e.  $T_{\alpha^+}^{-k} \circ T_{\beta^+}$  is positive in the  $\alpha$ -, but negative in the  $\beta$ -ordering.

*Proof of Theorem 3.4* (c). This is an immediate consequence of Theorem 7.4.  $\Box$ 

ACKNOWLEDGEMENTS. We are very grateful to W.P. Thurston for sharing with us his idea for the construction of orderings on  $\mathcal{MCG}(S)$ . We also thank the following people for helpful comments: S. Chmutov, D. Cooper, L. Paris, D. Rolfsen, C. Rourke, L. Rudolph, and M. Scharlemann. B.W. was supported by a TMR Marie Curie research training grant from the European Community.
