A VANISHING CONJECTURE FOR THE HOMOLOGY OF CONGRUENCE SUBGROUPS

by Dominique ARLETTAZ

For any prime number p , let $\Gamma_{n,p}$ denote the *congruence subgroup* of $\mathrm{SL}_n(\mathbf{Z})$ of level p , i.e., the kernel of the surjective homomorphism $f_p: \mathrm{SL}_n(\mathbf{Z}) \rightarrow \mathrm{SL}_n(\mathbf{F}_p)$ induced by the reduction mod p , and let us write $\Gamma_p = \varinjlim_n \Gamma_{n,p}$, where the limit is defined by upper left inclusions. Notice that the groups $\Gamma_{n,p}$ are not homology stable with \mathbf{Z} -coefficients (see [2]).

If p is odd, then the group Γ_p is torsion-free. Therefore, it is of particular interest to detect torsion classes in the integral (co)homology of Γ_p . It turns out that $H^*(\Gamma_p; \mathbf{Z})$ contains 2-torsion elements in arbitrarily large dimensions (see Corollary 1.10 of [1]). Groups like this are called groups with “very strange torsion” by S. Weintraub in 1986.

However, vanishing results for the (co)homology of Γ_p are also extremely useful. Let us propose the following

CONJECTURE 2.1. *For an odd integer n and an odd prime p , the homology group $H_n(\Gamma_p; \mathbf{Z})$ contains no q -torsion if q is a sufficiently large prime (in comparison to n), $q \neq p$.*

As far as I know, this problem is not solved, but one should notice its relationship with the study of the Dwyer–Friedlander map

$$\varphi_{\mathbf{Z}}: (K_n(\mathbf{Z}))_q \rightarrow K_n^{\text{ét}}(\mathbf{Z}[\frac{1}{q}])$$

relating the q -torsion of algebraic K -theory to étale K -theory. This map is known to be surjective and it is conjecturally an isomorphism (this is a version of the Quillen–Lichtenbaum conjecture, see [3], Theorem 8.7 and Remark 8.8).

For $q \neq p$, the Dwyer–Friedlander map and the reduction mod p induce the commutative diagram

$$\begin{array}{ccc} (K_n(\mathbf{Z}))_q & \xrightarrow{\varphi_{\mathbf{Z}}} & K_n^{\text{ét}}(\mathbf{Z}[\frac{1}{q}]) \\ \downarrow (f_p)_* & & \downarrow \\ (K_n(\mathbf{F}_p))_q & \xrightarrow{\varphi_{\mathbf{F}_p}} & K_n^{\text{ét}}(\mathbf{F}_p) \end{array}$$

The map $\varphi_{\mathbf{F}_p}$ is an isomorphism, since the K -theory of finite fields is completely known. If we define $A_n = \ker \varphi_{\mathbf{Z}}$ and $B_n = \ker (f_p)_*$, this implies that A_n is contained in B_n .

On the other hand, one can show by using Postnikov decompositions that B_n is a direct summand of $(H_n(\Gamma_p; \mathbf{Z}))_q$ for large enough primes $q \neq p$ (see [1], Introduction and Theorem 2.1).

Consequently, the proof of the above conjecture for n odd and q a large enough prime would imply the vanishing of B_n and therefore the vanishing of A_n which provides the assertion that the Dwyer–Friedlander map $\varphi_{\mathbf{Z}}$ is an isomorphism.
