New Type of Soliton Solutions from a Landau Potential Describing  
the  $\beta$ - $\gamma$ - $\delta$ -Transitions in  $(C_3H_7NH_3)_2MnCl_4$

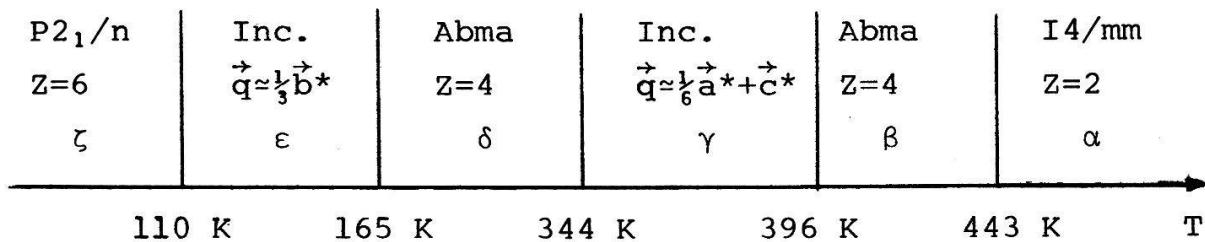

P. Muralt, R. Kind

Laboratory of Solid State Physics, Swiss Federal Institute  
of Technology, Hönggerberg, CH-8093 Zürich, Switzerland.

**Abstract:** The incommensurate  $\gamma$ -phase of the perovskite-type  
layer structure compound  $(C_3H_7NH_3)_2MnCl_4$  is sandwiched  
between two phases ( $\beta, \delta$ ) which have the same structure.  
The Landau potential describing this behaviour reveals  
besides the plane-wave solution also a new  
type of soliton solutions which differ from the solu-  
tions of the sine-Gordon equation.

### Introduction

Perovskite-type layer structures of the formula  
 $(C_nH_{2n+1}NH_3)_2MnCl_4$  with short hydrocarbon chains ( $n < 5$ ) are known  
to exhibit several structural phase transitions which are con-  
nected with reorientational jumps of the alkylammonium chains  
<sup>1</sup>. Within this family the compound  $(C_3H_7NH_3)_2MnCl_4$  is a spe-  
cial case because of its complicated phase sequence with two in-  
commensurate phases <sup>2,3</sup>. The different phases are denoted as  
 $\alpha, \beta, \gamma, \delta, \varepsilon$  and  $\zeta$ .

The most interesting feature is the reentrant behaviour  
of the  $\gamma$ - $\delta$ -transition. It was shown by means of NMR-NQR that the  
 $\beta$  and the  $\gamma$ -phase have indeed the same structure <sup>4</sup>. They differ  
only in the saturation of the order parameter of the  $\alpha$ - $\beta$ -transi-  
tion. This reentrant behaviour could be well described by a

Landau-type free energy /4/. It was shown that a plane wave modulation is an exact solution of the corresponding Euler equations. In this contribution we want to stress also soliton-like solutions in order to explain the observed types of x-ray satellite reflections.

#### Incommensurate Wave Vectors of the $\gamma$ -Phase

An x-ray analysis of the  $\gamma$ -phase revealed three types of satellite reflections /2/:

type A1:  $\vec{q}_1 = \alpha \vec{a}^* + \vec{c}^*$ ,  $\alpha \approx 0.17$ , strong  
 A2:  $\vec{q}_2 = 2\alpha \vec{a}^*$ , weak  
 B:  $\vec{q}_3 = \beta \vec{a}^* + \vec{c}^*$ ,  $\beta \approx 0.05$ , weak

$\vec{q}_1$  and  $\vec{q}_3$  are zone-boundary vectors on the H line near the Y point,  $\vec{q}_2$  is on the A line (notation according to ref.5). The type A2 satellites are obviously due to a higher harmonic of the type A1 modulation and are generated by a third-order anharmonic potential  $V_3(Q_{q_1-q_2}^2 + Q_{-q_1-q_2}^2)$ . The origin of the B-type modulation is still an open question.

The commensurate part of the modulation ( $=\vec{c}^*$ ) destroys the A-centering of the unit cell. The superspace group compatible with the A1 reflections is  $N_{111}^{Abma}$  /2/. The soft mode leading to this superspace group must transform according to the irreducible representation  $H_1$ , which splits at the Y point into the one-dimensional representations  $Y_1^+$  and  $Y_3^-$  having at the  $\Gamma$  point  $x^2$  and  $x$  symmetry respectively. At the Y point there is no degeneracy of modes and therefore no Lifshitz invariant is allowed. At the other end of the H line, at the T point ( $\frac{1}{2}\vec{a}^* + \vec{c}^*$ ), all modes are doubly degenerate and Lifshitz invariants can be formed. The mode softening with a wave vector close to the Y point is in our case due to a coupling of two modes with  $Y_1^+$  and  $Y_3^-$  symmetry.

---

\*)  $\vec{a}^*$ ,  $\vec{b}^*$ ,  $\vec{c}^*$  are given for the A-centered unit cell.

### Thermodynamic Potential and Discussion of the Euler Equations

A free energy explaining the reentrant behaviour of the  $\gamma$ - $\delta$ -transition is given in ref. 4. A coupling of the order parameter with the density of the layers leads to renormalized Landau coefficients  $\hat{A}(T)$  and  $\hat{B}(T)$  containing both linear and quadratic terms in  $(T-T_0)$ . Outside the  $\gamma$ -phase the density of layers must exhibit a linear term in the temperature dependence to provide the reentrant behaviour. The free energy density is thus given by:

$$g = g_0 + \frac{1}{2} \hat{A} \eta \eta^* + \frac{1}{4} \hat{B} (\eta \eta^*)^2 - \frac{1}{2} \kappa \frac{d\eta}{dx} \frac{d\eta^*}{dx} + \frac{1}{2} \lambda \frac{d^2\eta}{dx^2} \frac{d^2\eta^*}{dx^2}, \quad \kappa, \lambda > 0$$

The plane wave  $\eta = A e^{i q_0 x}$  ( $A = \text{const.}$ ,  $q_0^2 = \kappa/2\lambda$ ) is an exact solution of the resulting Euler equations. A more general solution can be obtained within a constant-amplitude approximation ( $\eta = A e^{i \Phi(x)}$ ,  $A = \text{const.}$ ). In this case  $\Phi$  can be expressed in terms of elliptic integrals of the first kind. Introducing the function

$h = \frac{1}{q_0^2} \cdot \left( \frac{d\Phi}{dx} \right)^2 - 1$  the Euler equation for the phase  $\Phi$  reads after one integration:

$$\left( \frac{dh}{dx} \right)^2 = 4 q_0^2 (h+1)(h^2 - \mu^2) \quad \mu: \text{integration const.}$$

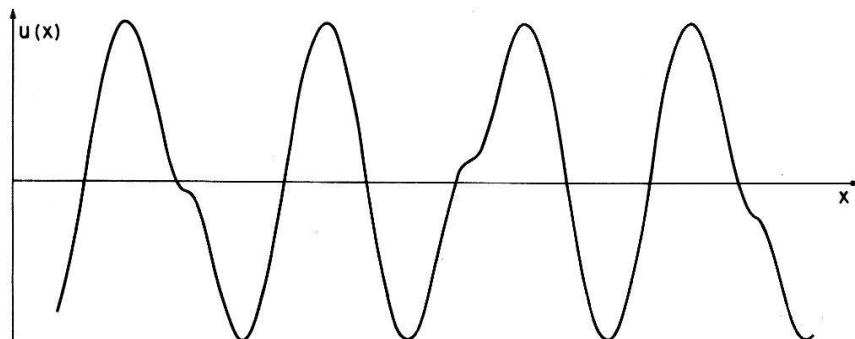

Fig. 1 Normalized atomic displacement  $u(x) = \sin(\phi(x))$  for  $k = \sin^{-1}(89^\circ)$ .

The solution can be evaluated by the integral

$$x = \sqrt{\frac{1}{1+\mu}} \frac{1}{q_0} \int_0^y \frac{dy}{\sqrt{1-k^2 \sin^2 y}}, \quad h = -1 + (1-\mu) \sin^2 \varphi, \quad k^2 = \frac{1-\mu}{1+\mu}$$

or written in a condensed form:

$$\phi = \int_0^x \sqrt{1+h(x')} dx', \quad h(x) = -1 + (1-\mu) \sin^2(\sin(q_0 \sqrt{1+\mu} x))$$

In the plane-wave case,  $h=0$ ,  $\mu=0$  and  $k=1$ .

Some results are shown in Figures 1 and 2. In contrast to the solution of the sine-Gordon equation where only higher harmonics are obtained our equation leads also to "subharmonic" parts which would explain the B-type x-ray reflections.

By introducing  $h$  into the free energy  $F = \int g dV$  one gets:  $F = F_0 + V \left\{ \frac{1}{2} \left[ \hat{A} + \lambda q_0^4 (-1 + H(k)) \right] A^2 + \frac{1}{8} \hat{B} A^4 \right\}$

$$H(k) \approx 2 \langle h^2 \rangle - \frac{1-k^2}{1+k^2}.$$

The average of  $h^2$  is given by  $\langle h^2 \rangle = \frac{\int \frac{1}{2} h^4(y) dy}{\int \frac{1}{2} dy} / \int \frac{dy}{\sqrt{1-k^2 \sin^2 y}}$ .

The minimum of  $F$  with respect to  $k$  is obviously independent of  $A$  and coincides with the minimum of  $H(k)$ . This function is shown in Fig. 3. It can be seen that the plane-wave solution ( $k=1$ ) has a lower free energy than a solution with a space-dependent  $\frac{d\Phi}{dx}$ . However, our free energy contains only the leading terms necessary to explain both, the incommensurability and the reentrant behaviour. A complete free-energy density up to the fourth order of

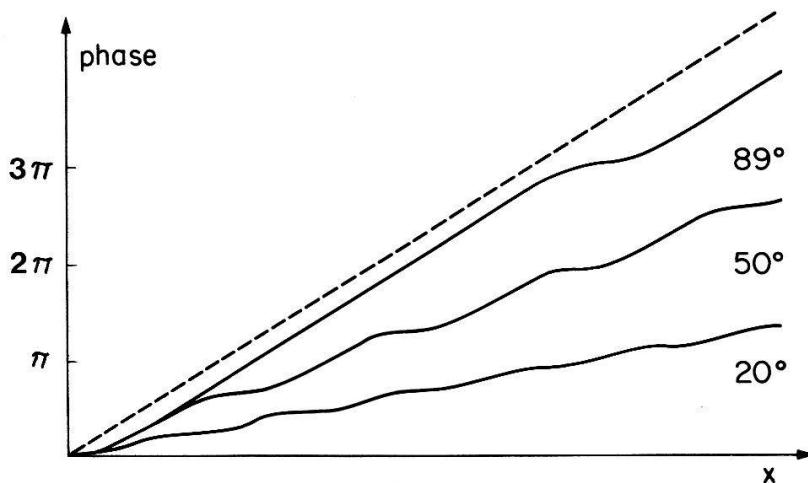

Fig. 2 Phase angle  $\phi$  vs.  $x$  for different values of  $\sin^{-1}(k)$ .  
The dashed line corresponds to the plane-wave solution.

The function  $H$  (as defined on the preceding page) vs.  $\sin^{-1}(k)$ .

the amplitude should also take into account the terms  $\sigma \left( \frac{dn}{dx} \frac{dn^*}{dx} \right)^2$  and  $\rho \left( \frac{d^2n^*}{dx^2} \frac{d^2n}{dx^2} \right)^2$ . Especially the first of these terms with  $\sigma > 0$  would favour a solution with  $k < 1$ , since with lower  $k$  the value of  $\left\langle \frac{d\Phi}{dx} \right\rangle$  is reduced.

The effect of a space-dependent amplitude can not be predicted since it would require the solution of two coupled strongly non-linear Euler equations. It was shown/6/, however, that the amplitude variations do not play an essential part in modulated structures of the  $\beta\text{-K}_2\text{SO}_4$  family.

To conclude we can say that our Landau potential doesn't only describe the reentrant behaviour but also explains all kinds of the observed x-ray satellites. The crucial experiment to test our theory should be the measurement of the temperature dependence of the splitting and the intensity of the B-type reflections.
