(9.1.1996)

Abstract. Extended Version of AKS theorem is used in conjunction with co-cycle and moment map to derive some new integrable systems in loop algebra. In the first case we get equations like, three wave interaction, second order matrix nonlinear system, while in the case of moment map we obtain generalizations of dispersive water wave equation and MKdV system.

1 Introduction

The Adler–Kostant–Symes theorem [1] is one of the most important tools for the construction and investigation of the properties of nonlinear integrable systems. The AKS theorem gives a purely Lie theoretic setting to the study of such systems. Whether the underlying Lie algebra is finite or infinite dimensional, the theorem can always be used to construct the integrable equation. Its use provides a Lax pair and a Hamiltonian structure just by construction. Moreover, the complete integrability of the nonlinear dynamical systems [2] so constructed, is always guaranteed due to Liouville’s theorem, which demands the existence of an infinite number of conserved quantities in involution.

On the other hand, moment maps [3] have also been used in relation to integrable systems. Efforts have been made to provide a systematic link between integrable systems, flows in loop algebras and integrable systems of partial differential equations through the use of moment maps. The construction of such maps allows us to apply the results of the AKS theorem to derive large class of integrable systems from the commutativity of the flows.
In the present paper, we follow a generalization of the AKS theorem due to Reyman et al [4] to derive some new integrable systems in loop algebra. Among these is the three wave interaction system which is of considerable interest in plasma physics [5], later in the paper, we utilize the moment map construction along with the extended AKS theorem to deduce some more integrable equations among which are the familiar mKdV and the generalized Nonlinear Schrödinger and dispersive water wave equations.

Let us outline the motivation for this paper. Although the AKS theorem has been around for quite some time, we felt that its application in obtaining new as well as interesting integrable systems is fairly nontrivial and therefore worth studying. Moreover, the use of the extended AKS theorem in the back drop of the moment map technique seems to be a pretty interesting formalism.

Our paper is organized as follows. In section 2, we introduce the extended AKS theorem in the context of loop algebra and use it in section 3 to derive some new integrable systems. In section 4 we introduce the moment map concept and study Poisson commutativity via the extended AKS theorem, Finally in section 5 we derive some coupled integrable PDEs by using the formulation of section 4.

2 The Loop algebra and the extended AKS Theorem

Let $g$ be a finite dimensional Lie algebra which can be written as the vector space direct sum, $g = k \oplus n$, where $k$ and $n$ are not only subspaces but they are also subalgebras. Suppose we are adding a co-cycle with $g$, then $g^* = g \oplus \mathbb{R}$. Further, suppose that we have a non degenerate, ad–invariant bilinear form $\langle , \rangle: g^* \times g^* \rightarrow \mathbb{C}$; by means of which we can identify the dual of $g^*$, i.e. $\tilde{g}^*$. From this bilinear form one can identify $k^* \cong n^*$ and $n^* \cong k^*$, where $< k, k > = 0 = < n^*, n >$. Let $(x, a) \in g^*$ where $X \in g$ and $a \in \mathbb{R}$. Then we have the commutator bracket,

$$[(x, a), (y, b)] = ([x, y], \int \text{tr } xy')$$  (1)

On $g^*$, the defining bilinear form will be,

$$\langle (x, a), (y, b) \rangle = ab + \int \text{tr } xy$$  (2)

Let $\hat{g} = g^* \times C[\lambda, \lambda^{-1}]$ be the affine Lie algebra related to $g^*$, that is, the loop algebra of formal Laurent series in $\lambda$ with coefficients in $g^*$.

The Lie bracket on $\hat{g}$ is defined by

$$[(\sum_{i=r}^{s} x_i \lambda^i, a(\lambda)), (\sum_{j=k}^{l} y_j \lambda^j, b(\lambda))] = \sum_{i=r}^{s} \sum_{j=k}^{l} [x_i, y_j] \lambda^{i+j}, \text{Res}(\text{tr } \int (\sum_{i} x_i \lambda^i)(\sum_{j} y_j \lambda^j))$$  (3)

With this preparation we can now state the basic idea of AKS Theorem. Let $L$ be a co-adjoint orbit (which is actually the Lax operator under consideration) through an element
of the Lie algebra, then the AKS theorem asserts,

$$\frac{\partial L}{\partial t} = [L, \pi_n(\nabla H)] + \partial_x(\pi_n(\nabla H))$$

(4)

\(\pi_n\) denoting projection on the subalgebra \(n\) and \(\nabla H\) are \(\text{ad}^*\) invariant functions obtained as solution of the equation

$$[L, \nabla H] + \partial_x(\nabla H) = 0$$

(5)

Let us now introduce the extended AKS theorem due to Reyman et al. [4]. An element \(Y\) of \(n^* \sim k^\perp\) is called an (infinitesimal) character of \(n\) if

$$[X, Y]_{k^\perp} = 0 \forall X \in n$$

(6)

Let \(I_Y\) be defined by \(I_Y(\mu) = I(\mu + Y), \mu \in g^*\).

Now, \([X, Y] = \sum_{i=-\infty}^{\infty} \sum_{j=0}^{\infty} [a_i, b_j] \lambda^{i+j}\). For \([X, Y] = 0\) the commutator must contain only negative powers of \(\lambda\). Hence, the only allowed value of \(j\) which satisfies (6) is \(j = 0\). Then in the loop algebra case, we have \(Y(\lambda) = Y, Y \in g\) is a character of \(n\).

It is now easy to deduce that in case of the extended AKS theorem, the \(\text{ad}^*\) – invariant ring of functions which are in involution will be determined from the condition,

$$[L', \nabla H(L')] + \partial_x(\nabla H(L')) = 0$$

(7)

where

$$L' = L + Y$$

(8)

The Hamiltonian flow is given by an equation of the following form,

$$L_t = [L', \pi_n(\nabla H(L'))] + \partial_x(\pi_n(\nabla H(L')))$$

(9)

In equations (4) and (9) the derivative is with respect to the spatial coordinate \(x\).

3 Integrable Systems via Extended AKS Theorem

Before applying the extended AKS theorem to derive new integrable systems, it is necessary to calculate explicitly the co-adjoint orbit in \(n^\perp\). We assume, without any loss of generality, that \(g\) is already in a faithful, linear representation.

Let \(\delta = \lambda^{-3} M \in n^\perp \subseteq K^*\) and let \(\Theta_{\delta}\) be the co-adjoint orbit in \(k^*\) generated by \(\phi \in \exp(k)\). Then a general element \(L\) in \(\Theta_{\delta}\) is given by [6,7],

$$L(\lambda) = [\phi^{-1} \delta \phi]_\perp = [\exp(- (\lambda \xi_1 + \lambda^2 \xi_2 + ...)) \lambda^{-3} M \exp((\lambda \xi_1 + \lambda^2 \xi_2 + \lambda^3 \xi_3)]_\perp$$

$$= \lambda^{-3} A + \lambda^{-2} B + \lambda^{-1} E$$

(10)

Here \(A, B\) and \(E\) are functions determined by \(M, \xi_1, \xi_2,\) etc., \([ \ ]_\perp\) denotes the projection into the sub algebra \(n\).
In case of the extended AKS theorem, the orbit will be given by (8).

To determine the $\text{ad}^*$ invariant functions, we take

$$\nabla H = \sum_{k=0}^{\infty} \lambda^{-3} k_{-3}$$

and use (7). Easy calculation shows that,

$$\pi_n(\nabla H) = \lambda^{-3} A + \lambda^{-2} B + \lambda^{-1} E$$

which is the second Lax operator for the integrable equation to be deduced below. Equation (9) leads to the following Hamiltonian flows,

$$A_t = [Y, A] + A_x, \quad B_t = [Y, B] + B_x, \quad E_t = [Y, E] + E_x$$

Equation (13) shows clearly how the extended AKS theorem gives rise to nonlinearity in the system. Setting $Y = 0$ would give a linear system of equations. Choosing $Y = A + B + E$, we arrive at the following system of equation,

$$A_t = [B + E, A] + A_x, \quad B_t = [E + A, B] + B_x, \quad E_t = [A + B, E] + E_x$$

Equations (14) are similar to those for the system of three wave interaction encountered in plasma physics.

For clarity we write out the first of equations (13) in non–matrix form. Choosing $\text{SL}(2)$ as the underlying finite dimensional algebra and writing a general element $X$ of this element in the form,

$$X = X_1 \sigma_3 + X_2 \sigma_+ + X_3 \sigma_-$$

($\sigma_3, \sigma_+ \text{ and } \sigma_- \text{ being Pauli matrices}$) we obtain the system of equations,

$$A_{1t} = A_{1x} + Y_2 A_3 - Y_3 A_2, \quad A_{2t} = A_{2x} + 2(Y_1 A_2 - Y_2 A_1), \quad A_{3t} = A_{3x} + 2(Y_3 A_1 - Y_1 A_3)$$

It is apparent that application of the usual AKS theorem ($Y_1 = Y_2 = Y_3 = 0$) would never give rise to the nonlinear system of equations (16).

As another example of our formalism, we take the orbit as

$$L' = \lambda^{-2} A + \lambda^{-1} B + Y$$

Taking

$$\nabla H = \sum_{k=0}^{\infty} \lambda^{k-1} h_{k-1}$$

and proceeding as before, we arrive at,

$$\pi_n \nabla H(L') = \lambda^{-1} A$$
which is the second Lax operator for this problem. Use of equation (9) leads to

$$A_t = [B, A], \quad B_t = [Y, A] + A_x$$

(20)

If we take $Y$ to be a consistent matrix and $A = W_t$ then equation (20) gives

$$W_{ttt} = [[Y, W], W_t] + [W_x, W_t]$$

(21)

This second order nonlinear matrix system was considered by Calogero [8] earlier. Again it is clear that use of the usual AKS theorem would not lead to equation (21), We write out (21) in non-matrix form as follows:

$$W_{1tt} = 2y_1(W_2W_3t + W_3W_2t) - 2y_2W_1W_3t - 2y_3W_1W_2t + W_{2x}W_3t - W_{3x}W_2t$$

(22)

$$W_{2tt} = 2y_2(W_3W_2t + 2W_1W_{1t}) - 2y_3W_2W_2t - 4y_1W_2W_{1t} + 2(W_{1x}W_2t - W_{2x}W_{1t})$$

(23)

$$W_{3tt} = 2y_3(2W_1W_{1t} + W_2W_3t) - 4y_1W_3W_{1t} - 2y_2W_3W_2t + 2(W_{3x}W_{1t} - W_{1x}W_3t)$$

(24)

It is clear that there is no triviality or overdeterminacy in the system of equations (22-24).

Furthermore, examples of new integrable systems may be constructed following the procedure outlined above.

4 Moment Maps

We first recapitulate the necessary definitions regarding moment maps. More details can be found in [3].

Let $(M, \omega)$ be a symplectic manifold, for $f \in C^\infty(M)$ the associated Hamiltonian vector field $X_f$ is defined by

$$X_f \lhd \omega = df$$

(25)

and the Poisson bracket in $C^\infty(M)$ is:

$$\{f, g\} = -X_f(g)$$

(26)

Then $C^\infty(M)$ may be regarded as a Lie algebra with respect to the Poisson–Lie bracket and denoting the Lie algebra of vector fields on the manifold $M$ by $\chi(M)$, the map

$$\beta : C^\infty(M) \rightarrow \chi(M), \beta(f) = -X_f$$

(27)

is a homomorphism of Lie algebras.

Let $\phi : G \times M \rightarrow M$ be a smooth group action preserving $\omega$ and denote by $\hat{G}$ the Lie algebra of $G$. The infinitesimal $\hat{G}$ action is given by the homomorphism [9,10].

$$\sigma : \hat{G} \rightarrow \chi(M), \quad \sigma(\xi)(x) = -\left. \frac{d}{dt} \phi(\exp(t\xi), x) \right|_{t=0}, \quad \xi \in \hat{G}, \ x \in M$$

(28)
The $G$ action is called Hamiltonian if there exists a moment map:

$$J : M \to \hat{G}^*$$

such that the hamiltonian flow generated by $\langle j, \xi \rangle$ coincides with $x \to \phi(\exp(t\xi), x)$, i.e.

$$X_{\langle j, \xi \rangle} = \sigma(\xi) \quad (29)$$

Let $M_{N,r}$ be the space of complex $N \times r$ matrices, and let us identify $M_{N,r} \sim M_{N,r}^*$ via the pairing

$$(F,G) = \text{tr}(E^T G), F,G \in M_{N,r} \quad (30)$$

Let us consider several group actions on $M_{N,r} \times M_{N,r}$ which are hamiltonian with respect to the symplectic form

$$\omega = \text{tr}(dF \wedge dG^T) \quad (31)$$

For $n \leq N$ let

$$G^n_r = GL(r, C) \times \ldots \times GL(r, C) \quad (n \text{ times}) \quad (32)$$

be the direct product Lie group and

$$\hat{G}^n_r = gl(r, C) \bigoplus \ldots \bigoplus gl(r, C) \quad (n \text{ times}) \quad (33)$$

be its Lie algebra.

Let $K_1, K_2, \ldots, K_n$ be positive integers with $K_i < r$ and $\sum_{i=1}^n K_i = N$. For $F \in M_{N,r}$, let $F_i$ denote the $K_i \times r$ block whose $j$-th row is the $(K_1 + \cdots + K_{i-1} + j)$-th row of $F$; i.e. $F$ has the block form

$$F = \begin{pmatrix} F_1 \\ \vdots \\ F_i \\ \vdots \\ F_n \end{pmatrix}$$

Now, let us define a Hamiltonian $G^n_r$ action on $M_{N,r} \times M_{N,r}$ by

$$(g(F,G))_i = (F_i g_i^{-1}, G_i g_i^T), g = (g_1 \ldots g_n) \quad (34)$$

Let $\sigma_i^n : G^n_r \to \chi(M_{N,r} \times M_{N,r})$ denotes the corresponding infinitesimal action. The associated moment map $J_i^n : M_{N,r} \times M_{N,r}(\hat{G}^n_r)^*$ is given by

$$J_i^n(F,G)(X_1, X_2, \ldots, X_n) = -\sum_{j=1}^n \text{tr}(F_j X_j G_j^T) \quad (35)$$

Identifying $gl(r, C)^*$ with $gl(r, C)$ through the trace of matrix products, and hence $(\hat{G}^n_r)^*$ with $\hat{G}^n_r$, we obtain,

$$J^n_i(F,G) = -(G_1^T F_1, G_2^T F_2, \ldots, G_n^T F_n) \in \hat{G}^n_r \quad (36)$$
Let us now return to our loop algebra situation. We follow the notations of section 2. However, in contrast to the def. of the inner product introduced there, here we define the non-degenerate ad-variant inner product by

\[ \langle X(\lambda), Y(\lambda) \rangle = \text{tr}((X(\lambda) Y(\lambda))_0) = \text{res}(\lambda = 0) \text{tr}(\lambda^{-1} X(\lambda)Y(\lambda)) \]  

(37)

where \( X(\lambda) Y(\lambda)_0 \) denotes the constant term in the formal series \( X(\lambda), Y(\lambda) \). Using (49), we have the identification

\[ (gl(r))^+ \sim (gl(r))^- = gl(r)_0 \]  

(38)

Let us now fix \( n \) distinct complex numbers \( \lambda_1, \lambda_2, ..., \lambda_n \). Since \( X(\lambda) \in gl(r)^+ \) is a polynomial we can evaluate at \( \lambda = \alpha_i \) to obtain \( X(\alpha_i) \in gl(r, C) \). This gives a Lie algebra homomorphism \( A : gl(r)^+ \to G^n_r \) defined by

\[ A(X(\lambda)) = (X(\alpha_1), X(\alpha_2), ..., X(\alpha_n)) \]  

(39)

The kernel of this map is \( a(\lambda) gl(r)^+ \), where \( a(\lambda) = \prod_{i=1}^n (\lambda - \alpha_i) \). Hence we have the exact sequence of Lie algebra homomorphisms:

\[ 0 \to a(\lambda) gl(r)^+ \to \to (I) gl(r)^+ \to (A) G^n_r \to 0 \]

where \( I \) is inclusion. The dual sequence is thus

\[ 0 \to (G^n_r)^* \to (A)^* (gl(r)^+)^* \to (I)^* (a(\lambda) gl(r)^+)^* \to 0 \]

(40)

If we identify \((G^n_r)^* \) with \( (G^n_r)^* \) by using the trace component wise, and \((gl(r)^+)^* \) with \((gl(r)^-)_0 \) we get

\[ A^* (Y_1...Y_n) = \lambda \sum_{i=1}^n \frac{Y_i}{\lambda - \alpha_i} = \sum_{k=0}^\infty \sum_{i=1}^n Y_i \alpha_i^k \lambda^{-k} \]  

(41)

Using (39) and (41) we arrive at the following expression for the moment map \( \bar{J}. \)

For \((F,G) \in M_{N,r} \times M_{N,r}\) we have

\[ \bar{J}_r(F,G) = \sum_{i=1}^n \frac{\lambda G_i^T F_i}{\alpha_i - \lambda} \]  

(42)

where we identify \((gl(r)^+)^* \) with \( gl(r)_0^- \)

For further formulation, let us consider the loop algebra \( sl(2,C) \). Denote the column vectors of \( F \) by \( \frac{1}{\sqrt{2}}(\bar{x}, \bar{y}) \) where \( \bar{x}, \bar{y} \in C^n \). Those of \( G \) are then \( \frac{1}{\sqrt{2}}(-\bar{y}, \bar{x}) \) and the symplectic form is given by \( \omega = d\bar{x} \wedge d\bar{y} \). This follows from the fact that in the \( sl(2,C) \) case we can take \( G = FY_1 \) where \( Y_1 = \sigma_+ - \sigma_- \). The moment map for the \( sl(2,C) \) action is

\[ \bar{J}_2(\bar{x}, \bar{y}) = \frac{\lambda}{2} (Q_\lambda(\bar{x}, \bar{y})\sigma_3 + Q_\lambda(\bar{y}, \bar{x})\sigma_1 - Q_\lambda(\bar{x}, \bar{x})\sigma_- \]  

(43)
where

\[ Q_\lambda(\vec{\xi}, \vec{\eta}) = \sum_{i=1}^{n} \frac{\xi_i \eta_i}{\lambda - \alpha_i} \]  \hspace{1cm} (44)

and \( \vec{\xi} = (\xi_1, \xi_2, \ldots, \xi_n), \vec{\eta} = (\eta_1, \eta_2, \ldots, \eta_n) \in \mathbb{R}^n \) and we now have the expression for \( \hat{\phi}_Y \) as,

\[ \hat{\phi}_Y(X(\lambda)) = \hat{\phi}(X(\lambda) + \lambda Y) \]  \hspace{1cm} (45)

where \( Y \in \mathfrak{sl}(2, \mathbb{C}) \) and \( \hat{\phi} \in I(\mathfrak{sl}(2)^*) \). We shall now try to generate new integrable systems by using the concept of the moment map in conjunction with the extended AKS Theorem.

To this end, let \( N(\lambda) = \tilde{J}_2(\vec{x}, \vec{y}) \) and define \( N'(\lambda) = N(\lambda) + \lambda Y \), write

\[ L'(\lambda) = \frac{a(\lambda)}{\lambda^n} N'(\lambda) = L(\lambda) + \frac{a(\lambda)}{\lambda^{n-1}} Y \]  \hspace{1cm} (46)

where

\[ L(\lambda) = \frac{a(\lambda)}{\lambda^n} N(\lambda) \]  \hspace{1cm} (47)

We take,

\[ L(\lambda) = L_0 + L_1 \lambda^{-1} + L_2 \lambda^{-2} + \ldots + L_{n-1} \lambda^{-n-1} \]  \hspace{1cm} (48)

\[ \lambda \frac{a(\lambda)}{\lambda^n} = \lambda + a_1 + \lambda^{-1} a_2 + \ldots + \lambda^{-(n-1)} a_n \]  \hspace{1cm} (49)

Consider the ad* invariant functions on \( SL(2, \mathbb{C})^* \) given by

\[ \phi_k(X, \lambda) = \frac{1}{2} \text{tr} \left( \frac{a(\lambda)}{\lambda^n} (X(\lambda)^2) \right) \]  \hspace{1cm} (50)

and let \( t_k \) denote the time parameter for the Hamiltonian flow of \( \hat{\phi}_k \). Then we have the equation of motion, as

\[ \frac{d}{dt_k} N(\lambda) = \left[ \frac{a(\lambda)}{\lambda^n} N'(\lambda), N'(\lambda) \right] \]  \hspace{1cm} (51)

\[ \frac{d}{dt_k} \left( \frac{\lambda^n}{a(\lambda)} L(\lambda) \right) = \left[ (\lambda^k L'(\lambda))_+, \frac{\lambda^n}{a(\lambda)} L'(\lambda) \right] \]  \hspace{1cm} (52)

\[ \frac{d}{dt_k} L(\lambda) = \left[ (\lambda^k L'(\lambda))_+, L'(\lambda) \right] \]  \hspace{1cm} (53)

In particular,

\[ L'(\lambda) = \lambda Y + (L_0 + a_1 Y) + (L_1 + a_2 Y) \lambda^{-1} + \ldots + (L_{n-1} + a_n Y) \lambda^{-(n-1)} \]  \hspace{1cm} (54)

It may be noted that the Lax equation (53) is constructed with the help of the moment map - \( N(\lambda) = \tilde{J}_2 \)

Having completely described the formulation of the extended AKS Theorem in the context of the moment map, we can now use this procedure to generate new integrable systems. This will be discussed in the next section. Obviously, we can take \( Y = 0 \) and thereby return to the AKS Theorem and construct integrable systems also from there. Further, we can use automorphisms of the Lie algebra to generate integrable systems starting from the AKS Theorem. All these will be done in the next section.
5 Some Integrable Systems using Moment Map.

Example I

Let us take \( k = 0 \) and \( k = 1 \) successively in (53). Then we obtain the first few nontrivial equations as follows

\[
\frac{dL_0}{dt_0} = [Y, L_1] \tag{55}
\]

\[
\frac{dL_1}{dt_0} = [L_0, L_1] + [Y, L_2 + a_1L_1 - a_2L_0] \tag{56}
\]

and

\[
\frac{dL_0}{dt_1} = [Y, L_2] \tag{57}
\]

An invariant of the flows is \( \frac{1}{2} \) \( \text{tr} (L'(\lambda))^2 \) which when taken as zero and \( L'(\lambda) \) substituted reduces to,

\[
\text{tr} [YL_1 + L_1Y + 2a_2Y^2 + L_0^2 + a_1^2Y^2 + a_1(L_0Y + YL_0)] = 0 \tag{58}
\]

Taking

\[
Y = Y_1\sigma_3 + Y_2\sigma_+ + Y_3\sigma_- \quad L_0 = a\sigma_3 + b\sigma_+ + c\sigma_- \quad L_1 = s\sigma_3 + v\sigma_+ + w\sigma_- \quad L_2 = s\sigma_3 + v\sigma_+ + w\sigma_-(59)
\]

we obtain, from above, the following sets of equations

\[
a_x = Y_2u - Y_3v, \quad b_x = 2(Y_1v - Y_2s), \quad c_x = (Y_3s - Y_1u) \tag{60}
\]

\[
s_x = bu - cv + (Y_2U - Y_3V) + a_1(Y_2u - Y_3v) - a_2(Y_2c - Y_3b) \tag{61}
\]

\[
v_x = 2(av - bs) + 2(Y_1v - Y_2s) + 2a_1(Y_1v - Y_2s) - 2a_2(Y_1b - Y_2a) \tag{62}
\]

\[
U_x = 2(cs - au) + 2(Y_3s - Y_1u) + 2a_1(Y_3s - Y_1u) - 2a_2(Y_3a - Y_1c) \tag{63}
\]

and

\[
a_t = Y_2U - Y_3V, \quad b_t = 2(Y_1V - Y_2s), \quad c_t = 2(Y_3s - Y_1U) \tag{64}
\]

where we have taken \( t_0 \equiv x \) and \( t_1 \equiv t \).

\[
(a^2 + bc) + 2sY_1 + (vY_3 + uY_2) + (2a_2 + a_1^2)(Y_1^2 : + Y_2Y_3) + a_1(2a_1Y_1 + bY_3 + cY_2) = 0 \tag{65}
\]

Instead of pursuing the general case, which will be too complicated we shall now consider two special cases as follows:

**Case 1:** \( Y_2 = Y_3 = 0, Y_1 = \text{const.} \) whence we obtain \( a_x = 0a_t \) whereby \( a = 0 \) (by choice)

\[
b_x = 2Y_1v, \quad c_x = -2Y_1u \tag{66}
\]

\[
b_t = 2Y_1V, \quad c_t = -2Y_1U \tag{67}
\]
\[ s_x = bu - cv, \quad u_x = -2bs + 2Y_1 V + 2a_1 Y - 1u - 2a_2 Y_1 b, \quad u_x = 2cs - 2Y_1 U - 2a_1 Y_1 u + 2a_2 Y_1 c, \quad b_c + 2sY_1 + (2a_2 + a_1^2) Y_1^2 = 0 \]

From the above equations, we finally obtain the flows

\[
b_t = \frac{1}{2Y_1} (b_{xx} - 2b^2 c - 2a_1 Y_1^2 b - a_1 b_x)
\]

\[
c_t = \frac{1}{2Y_1} (c_{xx} - 2b c^2 - 2a_1 Y_1^2 c - a_1 c_x)
\]

which is very similar to this NLS eqn.

**Case 2:** \( Y_1 = 0, Y_2, Y_3 \) constants. Proceeding as in case 1, we obtain the flows,

\[
a_t = -\frac{1}{2Y_2} (b_{xx} - 2a^2 b) - \frac{Y_3}{Y_2^2} b^3 + a_1 Y_2 b - a_1 a_x
\]

\[
b_t = -\frac{1}{2Y_3} (a_{xx} - 2a^3) - \frac{a b^2}{Y_2} + a_1^2 Y_2 a - a_1 b_x
\]

This is a generalization of the Dispersive Water Wave Equations (10).

**Example II**

For this example, we turn to the ordinary AKS Theorem and use it in conjunction with the moment map construction i.e setting \( Y = 0 \) and \( k = 0 \) and 2 successively we obtain the following nontrivial equations,

\[
\frac{dL_0}{dx} = 0, \quad \frac{dL_1}{dx} = [L_0, L_2], \quad \frac{dL_2}{dx} = [L_0, L_3] + [L_1, L_2], \quad \frac{dL_3}{dx} = [L_0, L_4] + [L_1, L_3]
\]

\[
\frac{dL_0}{dt} = 0, \quad \frac{dL_1}{dt} = [L_0, L_4]
\]

Since \( L_0 \) is conserved, we take \( L_0 = \frac{1}{2}(\sigma_3 + \sigma_+ + \sigma_-) \). Further, we take

\[
L_1 = s \sigma_3 + v \sigma_+ + u \sigma_-, \quad L_2 = S \sigma_3 + V \sigma_+ + U \sigma_-, \quad L_3 = S \sigma_3 + V_1 \sigma_+ + U_1 \sigma_-, \quad (76)
\]

The equations turn out to be:

\[
s_x = \frac{1}{2}(U - V), \quad u_x = V - S, \quad u_x = S - U
\]

\[
S_x = \frac{1}{2}(U_1 - V_1) + vU - uV, \quad U_x = S_1 - U_1 + 2(uS - sU), \quad V_x = V_1 - S_1 + 2(sV - vS)
\]

\[
s_t = : S - 1x - (U_1 - uV_1), \quad u_t = U_1x - 2(uS_1 - sU_1), \quad v_t = V_1x - 2(sV_1 - vS_1)
\]
We obtain the following connecting equations.

\[ U = -\frac{1}{4} V_x - \frac{3}{4} u_x - \frac{1}{2} (s^2 + uv), \quad V = \frac{3}{4} v_x - \frac{1}{4} u_x - \frac{1}{2} (s^2 + uv) \quad (80) \]

with

\[ V + U = -2s \quad (81) \]

We also have the invariant conditions

\[ S + \frac{1}{2} (U + V) + (s^2 + uv) = 0 \quad (82) \]

\[ S_1 + \frac{1}{2} (U_1 + V_1) + 2s s + uV + vU = 0 \quad (83) \]

which lead to relations,

\[ U_1 = \frac{1}{2} u_{xx} + \frac{1}{2} (u_x v - u v_x) - \frac{3}{2} u^2 v - \frac{1}{4} u v^2 - \frac{1}{4} u^3 \quad (84) \]

\[ V_1 = \frac{1}{2} v_{xx} + \frac{1}{2} (u_x v - u v_x) - \frac{3}{2} v^2 u - \frac{1}{4} v u^2 - \frac{1}{4} v^3 \quad (85) \]

and finally to the following coupled mKdV equations in \( u \) and \( v \),

\[ 4u_t = 2u_{xxx} - 3v^2 u_x - 3u^2 u_x - 18u u_x v, \quad 4v_t = 2v_{xxx} - 3u^2 v_x - 3v^2 v_x - 18uv v_x \quad (86) \]

**Example III**

For this example, consider the moment map

\[ \tilde{J}_2 (F, G) = \frac{\lambda}{2} \sum_{i=1}^{n} \frac{G_i^T F_i}{\alpha_i - \lambda} \quad (87) \]

where, for the \( sL(2, C) \) algebra under consideration, we have \( F_i = \frac{1}{\sqrt{2}} (\vec{x}, \vec{y}) \) and \( G_i = \frac{1}{\sqrt{2}} (-\vec{y}, \vec{x}) \) since \( \text{tr}(G_i^T F_i) = 0 \). Under the automorphism \( [9] \)

\[ \tilde{J}_2 (F, G) = H(\lambda) \tilde{J}_2 (F, G) H(\lambda)^{-1}, \quad \lambda \to \lambda' = g(\lambda) = q\lambda \quad (88) \]

where

\[ H(\lambda) = \sigma_3 + \lambda(q - 1)\sigma_+ \]

and we take \( q^2 = 1 \), and finally take \( q = -1 \). The moment map becomes,

\[ \tilde{J}_2 (F, G) = \frac{\lambda}{2} \sum_{i=1}^{n} \frac{G_i^T F_i}{\alpha_i - \lambda} + \frac{q\lambda}{2} \sum_{i=1}^{n} \frac{H(\lambda) G_i^T F_i H(\lambda)^{-1}}{\alpha_i - q\lambda} \quad (89) \]

Under further action with \( H(\lambda) \) and \( \lambda' = q\lambda \) we obtain

\[ H(\lambda) \tilde{J}_2 (F, G) H(\lambda)^{-1} = \hat{J}_2 (F, G) \quad (90) \]
which explicitly proves the automorphism in question. Written out in full, the moment map becomes,

\[ \tilde{J}_2(F, G) = \frac{\lambda}{2} \sum_{i=1}^{n} [A \sigma_3 + B \sigma_+ - D \sigma_-] \]  

(91)

where,

\[ A = \frac{\chi^2 X_i^2 + \lambda(X_i Y_i - \chi X_i^2)}{\chi^2 - \alpha_i^2} \]

\[ B = \frac{(-2\lambda^3 X_i^2 + \alpha X_i Y_i + 2\lambda^2(\alpha X_i^2 - X_i Y_i))}{\chi^2 - \alpha_i^2} \]

\[ D = \frac{\alpha_i X_i^2}{\chi^2 - \alpha_i^2} \]

Now choose \( N(\lambda) = \tilde{J}_2(F, G) \) and

\[ L(\lambda) = \chi^2 L^{(2)} + \lambda L^{(1)} + \lambda^{-2n-1} L_{2n-1} \]  

(92)

and the Lax form of the equation

\[ \frac{d}{dt_k} L(\lambda) = [(\lambda^{2k} L(\lambda))_+, L(\lambda)] \]  

(93)

where the invariants are given by,

\[ \phi_k(x(\lambda)) = \frac{1}{2} \text{tr} \left( \frac{\lambda^{2k} a(\lambda) x(\lambda)^2}{\lambda^{2n}} \right)_0 \]  

(94)

and \( t_k \) denotes the time parameter for the hamiltonian flow of \( \phi_k \).

\[ L^{(2)} = -2V^{(2)} \sigma_+ , \quad L^{(1)} = V^{(2)} \sigma_3 + V^{(1)} \sigma_+ , \quad L_0 = -\frac{V^{(1)}}{2} \sigma_3 \]  

(95)

\[ L_1 = u_1 \sigma_3 + V_1 \sigma_+ + \omega_1 \sigma_- , \quad L_2 = u_2 \sigma_3 + V_2 \sigma_+ , \quad L_3 = u_3 \sigma_3 + V_3 \sigma_+ + \omega_3 \sigma_3 , \quad L_4 = u_4 \sigma_3 + V_4 \sigma_+ \]  

(96)

Now let us set \( k = 1 \) and 2 successively in (93). Then we find \( L^{(2)} \) is conserved and hence we may set it equal to zero. In turn, this implies that \( L^{(1)} \) is conserved and therefore may be set equal to zero. Finally, we find that \( L_0 \) is conserved and may also be set to zero. Identifying \( t_1 \equiv x \) and \( t_2 \equiv t \), we obtain the following nontrivial equations:

\[ \frac{dL_1}{dx} = 0 , \quad \frac{dL_2}{dx} = [L_1, L_3] , \quad \frac{dL_3}{dx} = [L_1, L_4] + [L_2, L_3] , \quad \frac{dL_4}{dx} = [L_1, L_5] + [L_2, L_4] \]  

(97)

and

\[ \frac{dL_1}{dt} = 0 , \quad \frac{dL_2}{dt} = [L_1, L_5] \]  

(98)

from which we obtain,

\[ \frac{dL_2}{dt} = \frac{dL_4}{dx} - [L_2, L_4] \]  

(99)

Since \( L_1 \) is conserved set \( L_1 = \alpha \sigma_3 + \beta \sigma_+ + \gamma \sigma_- \) and for simplicity take \( \alpha = \beta = \gamma = 1 \). The explicit equations we get are the following:

\[ u_{2x} = \omega_3 - v_3 , \quad v_{2x} = 2(v_3 - u_3) , \quad u_3 = \omega_3 \]  

(100)
\[ u_{3x} = -v_4 + v_2 \omega_3 , \ \omega_{3x} = 2u_4 - 2u_2 \omega_3 , \ v_{3x} = 2(v_4 - u_4) + 2(u_2 v_3 - v_2 u_3) \]  
and the invariant
\[ \text{tr} \left[ \lambda^4 \left( L(\lambda)^2 \right)_0 \right] = \text{tr} \left[ L_1 L_3 + L - 3 L_1 + L_2^2 \right] = \text{constant} \]
From these relations, it is easy to obtain
\[ v_2 = -2u_2, -3 = \omega_3 = -\frac{1}{4} u_2^2 - \frac{1}{8} v_{2x}, v_3 = -\frac{1}{4} u_2^2 + \frac{3}{8} v_{2x}, v_4 = -2u_4 = -\frac{1}{4} u_{2xx} + \frac{1}{2} u_2^3 \]
Hence, we get the flow [12] as:
\[ 8u_{2t} = u_{2xxx} - 6u_2^2 u_{2x} \]
which is nothing but the mKdV equation.

6 Conclusion

In this paper, we have obtained some integrable systems via the extended AKS Theorem and the moment map technique. It is interesting to note that some new non linear equations along with those already known are deduced. The moment map formalism helps to reduce the number of dependent variables. An immediate extension is the application of the method to super-Lie algebra which will give rise to supersymmetric integrable system. The bi-Hamiltonian structure and other properties of these equation will be the subject of our future investigation. One of the authors (I.M.) is grateful to CSIR (Govt. of India) for a Fellowship.
