# Stably spherical classes in the $K$-homology of a finite group 

K. Knapp

## §1. Introduction

Let $G$ be a finite group and $B G$ its classifying space. In this paper we study the Hurewicz map

$$
h_{K}: \pi_{n}^{s}(B G) \rightarrow K_{n}(B G) .
$$

Here $\pi_{n}^{s}(X)$ denotes the stable homotopy and $K_{n}(X)$ the (reduced) $K$-homology of $X$; the homomorphism $h_{K}$ is induced by the unit map from the sphere spectrum to the spectrum of complex $K$-theory. Since $K_{n}(B G)=0$ for $n$ even, we assume $n$ to be odd. Somewhat surprisingly it turns out that for $n$ sufficiently large the image of $h_{K}$ is more accessible than for example im ( $h: \pi_{n}^{s}(B G) \rightarrow H_{n}(B G)$ ) or even $H_{n}(B G)$ itself. This simplicity in high dimensions is, of course, obscured by the fact that im ( $h_{K}$ ) can be rather complicated for small $n$.

The major results of this paper are (i) a computation of the odd primary part of im $\left(h_{K}: \pi_{2 n-1}^{s}(B G) \rightarrow K_{2 n-1}(B G)\right)$ for all but finitely many $n$ and (ii) a complete computation of the image for some small groups, e.g. $G=\mathbb{Z} / p, \mathbb{Z} / p^{2}$, $\mathbb{Z} / p \times \mathbb{Z} / p,(\mathbb{Z} / p \times \mathbb{Z} / p) \rtimes \mathbb{Z} / p$. To state (i) more precisely fix an odd prime $p$ and choose $l$ generating $\left(\mathbb{Z} / p^{2}\right)^{*}$. The Adams operation $\psi^{l}$ defines a stable operation $\psi_{n}^{l}$ on $p$-local $K$-homology $K_{n}(X)_{(p)}$ which acts as the identity on stably spherical classes. Therefore we have im $\left(h_{K}\right) \subset \operatorname{ker}\left(\psi_{n}^{\prime}-1\right)$. For $X=B G$ and $n$ large it turns out that $\psi_{n}^{l}-1$ gives the only restriction for an element to be stably spherical:

THEOREM 4.4. Let $G$ be a finite group and $p$ an odd prime. Then there exists $n_{0}(G, p) \in \mathbb{N}$ such that for $n \geq n_{0}(G, p)$ im $\left(h_{K}: \pi_{2 n-1}^{\prime}(B G)_{(p)} \rightarrow K_{2 n-1}(B G)_{(p)}\right)$ is the subgroup $\operatorname{ker}\left(\psi_{2 n-1}^{\prime}-1\right)$.

There is a similar result for $p=2$ with real $K$-theory.
One reason for being interested in $h_{K}: \pi_{2 n-1}^{s}(B G) \rightarrow K_{1}(B G)$ is the following relation to equivariant topology. First of all $\pi_{n}^{s}\left(B G^{+}\right)$can be identified with the equivariant bordism group $\Omega_{n}^{\text {fr }}(G)$ of free, equivariantly framed $G$-manifolds. By

Bott periodicity we have $K_{2 n-1}(B G)=K_{1}(B G)$. For any finite group $G$ there exists an embedding

$$
\psi: K_{1}(B G) \rightarrow \bar{R}(G) \otimes(\mathbb{Q} / \mathbb{Z})
$$

where $R(G)$ is the complex representation ring of $G, \bar{R}(G)=R(G) /(\mathrm{reg})$ and reg is the regular representation of $G$ (see $\S 2$ ). With respect to Pontrjagin duality $\psi$ is dual to the well known map

$$
\alpha: R(G) \rightarrow K^{0}\left(B G^{+}\right) .
$$

The Hurewicz map $h_{K}$ composed with $\psi$ has the following interpretation. Given $x$ in $\pi_{2 n-1}^{s}\left(B G^{+}\right)$, represent $x$ by a free, equivariantly framed $G$-manifold $M$. Since $\pi_{2 n-1}^{s}\left(B G^{+}\right)$is finite, some multiple of $M$, say $m \cdot M$, bounds a free $G$-manifold W

$$
m \cdot M=\partial W
$$

For $W$, the $G$-signature $\operatorname{sign}(W, G) \in R(G)$ is defined. The value of $\alpha(M, G):=$ $(1 / m) \operatorname{sign}(W, G) \in \bar{R}(G) \otimes \mathbb{Q}$ depends only on $M$ and is a bordism invariant in $\bar{R}(G) \otimes(\mathbb{Q} / \mathbb{Z})$. Then

$$
(-2)^{n} \cdot \psi^{\circ} h_{K}(x)=\frac{1}{m} \operatorname{sign}(W ; G)
$$

in $\bar{R}(G) \otimes \mathbb{Q} / \mathbb{Z}$. Thus a determination of $\operatorname{im}\left(h_{K}\right)$ shows which values the invariant $\alpha(M, G) \in \bar{R}(G) \otimes \mathbb{Q} / \mathbb{Z}$ can take on equivariantly framed free $G$ manifolds.

The paper is organized as follows. In $\S 2$ we collect the necessary facts about $K_{*}(B G)$ and its relation to $R(G)$ used in the rest of the paper. One main point is an investigation of the skeletal filtration of $K_{1}(B G)$.

In §3 we study the invariant $\operatorname{ker}\left(\psi_{2 n-1}^{l}-1\right)$. The fibre of the Adams operation $\psi_{n}^{l}-1$ defines a $p$-local homology theory $\operatorname{Ad}_{n}(X)$ and for $X=B G$ we have $\operatorname{ker}\left(\psi_{2 n-1}^{l}-1\right) \cong \operatorname{Ad}_{2 n-1}(B G)$. We show that for $n \neq 0 \operatorname{Ad}_{2 n-1}(B G)$ is a finite group annihilated by $e \cdot n$ where $e$ is the exponent of $G$. Because of the close relation to the representation ring, the structure of $\operatorname{Ad}_{2 n-1}(B G)$ can be determined more easily than for example that of $H_{*}(B G)$. For example, if $G$ is the symmetric group $\Sigma_{m}$ then $\operatorname{Ad}_{2 n-1}\left(B \Sigma_{m}\right)$ is isomorphic to $\oplus \mathbb{Z} / \boldsymbol{p}^{1+v_{p}(n)}$ for $n \equiv 0(p-1)$ and 0 otherwise $(n \neq 0)$. Here $v_{p}(n)$ denotes the exponent of $p$ in the prime decomposition of $n$. At least for a $p$-group there is an explicit description
of $\mathrm{Ad}_{2 n-1}(B G)$ in terms of the conjugacy classes of $G$; see (3.16). A universal coefficient formula for Ad-theory relating Ad-homology to Ad-cohomology gives, in the special case $X=B G$ and $n \neq 0$, an isomorphism $\operatorname{Ad}^{1+2 n}(B G) \cong$ $\operatorname{Ad}_{1-2 n}(B G)$, thus reducing the computation of $\mathrm{Ad}^{*}(B G)$ to that of $\mathrm{Ad}_{*}(B G)$.

In §4 we use a solution of the Adams conjecture to construct the elements necessary to generate im $\left(h_{k}\right)$ and prove theorem (4.4). The method used to construct elements in im $\left(h_{K}\right)$ relies on the fact that the skeletal filtration of the elements in question is small enough. This only works in dimensions larger than some $n_{0}(G) \in \mathbb{N}$ and seems to be a special property of the classifying space of a finite group. For $G$ abelian we give an explicit estimate for the constant $n_{0}(G)$. In the case of some small groups the bound $n_{0}(G)$ turns out to be small enough for the computation of im $\left(h_{K}\right)$ to be completed by other methods.

In $\S 5$ we deal with the case of a cyclic group $C$ in the dimension range $n \leqslant n_{0}(C)$. We show how im $\left(h_{K}\right)$ is related to the $e$-invariant on $\pi_{2 n-1}^{s}\left(B S^{1}\right)_{(p)}$ (this study was already begun in [10]) and give examples where im $\left(h_{K}\right)$ is acutally much smaller than $\operatorname{ker}\left(\psi_{2 n-1}^{l}-1\right)$. Results on $\pi_{2 n-1}^{s}\left(B S^{1}\right)$ (see e.g. [13]) may then be used to show that $\operatorname{im}\left(h_{K}\right)$ can be rather complicated in the range $n \leq n_{0}(G)$ - even for cyclic groups. We close with the example $G=\mathbb{Z} / p^{2}$.

The case $G=\mathbb{Z} / p$, reproved in §5, is already known. For $p=2 \mathrm{im}\left(h_{K}\right)$ was computed in [18], for $p \neq 2$ and $n \equiv 0(p-1)$ in [20] and for the other values of $n$ in [10].

We shall use the convention that all (co-)homology theories which occur will be taken as reduced theories. Throughout the paper we shall work at an odd prime $p$, but with some additional work many of the results carry over for $p=2$. The main result (4.4) is also true at $p=2$ and this is contained in remark (4.14).

I would like to thank M. Crabb, M. Hopkins and E. Ossa for valuable help and stimulating discussions. I also owe thanks to the Mathematics Department of the University of Warwick, where part of this work was carried out.

## 82. $K_{*}(B G)$ and the representation ring of $G$

Let $E G$ denote a free contractible $G$-space with $E G / G=B G$ and $\mathrm{pr}: E G^{+} \rightarrow$ $S^{0}$ the canonical projection. The map $\alpha: R(G) \rightarrow K^{0}\left(B G^{+}\right)$in Atiyah's theorem [2] may be viewed as the map induced by $p r$

$$
R(G)=K_{G}^{0}\left(S^{0}\right) \xrightarrow{\mathrm{pr}^{*}} K_{G}^{0}\left(E G^{+}\right) \cong K^{0}\left(B G^{+}\right)
$$

Here $K_{G}^{*}$ is reduced $G$-equivariant $K$-theory and we have used $K_{G}^{0}\left(X^{+}\right) \cong$ $K^{0}\left(X / G^{+}\right)$for a free $G$-space $X$. Dual to this, with $K_{*}^{G} G$-equivariant
$K$-homology, we have a map

$$
\begin{equation*}
\psi_{G}: K_{0}\left(B G^{+} ; \mathbb{Q} / \mathbb{Z}\right) \cong K_{0}^{G}\left(E G^{+} ; \mathbb{Q} / \mathbb{Z}\right) \xrightarrow{\mathrm{pr}_{.}} K_{0}^{G}\left(S^{0} ; \mathbb{Q} / \mathbb{Z}\right)=R(G) \otimes \mathbb{Q} / \mathbb{Z} . \tag{2.1}
\end{equation*}
$$

To deduce the properties of $\psi_{G}$ we relate $\psi_{G}$ to $\alpha$ via Pontrjagin duality. The $K$-theory Kronecker pairing

$$
\langle,\rangle_{K}: K^{i}(X) \otimes K_{i}(X ; \mathbb{Q} / \mathbb{Z}) \rightarrow \mathbb{Q} / \mathbb{Z}
$$

defines a linking form

$$
\begin{equation*}
L: K_{i}(X ; \mathbb{Q} / \mathbb{Z}) \rightarrow \operatorname{Hom}\left(K^{i}(X) ; \mathbb{Q} / \mathbb{Z}\right) . \tag{2.2}
\end{equation*}
$$

Since $\mathbb{Q} / \mathbb{Z}$ is injective as a $\mathbb{Z}$-module, Hom $\left(K^{i}(X) ; \mathbb{Q} / \mathbb{Z}\right)$ is a (non-additive) homology theory in $X$ and $L$ a natural transformation of homology theories. Clearly $L$ is an isomorphism on coefficients, hence $L$ is an isomorphism for finite $C W$-complexes. Let $B G^{(m)}$ denote the $m$-skeleton for a $C W$-structure on $B G$, then $L$ induces an isomorphism

$$
L: K_{i}(B G ; \mathbb{Q} / \mathbb{Z}) \cong \underset{m}{\lim } \operatorname{Hom}\left(K^{i}\left(B G^{(m)}\right) ; \mathbb{Q} / \mathbb{Z}\right)=: \operatorname{Hom}_{c}\left(K^{i}(B G) ; \mathbb{Q} / \mathbb{Z}\right) .
$$

The usual Kronecker pairing

$$
\langle,\rangle_{R}: R(G) \otimes R(G) \rightarrow \mathbb{Z}
$$

defined by $\langle\lambda, \mu\rangle_{R}:=\operatorname{dim} \operatorname{Hom}^{G}(\lambda, \mu)$ (e.g. see [19], §7) is nonsingular and induces an isomorphism

$$
L_{R}: R(G) \otimes \mathbb{Q} / \mathbb{Z} \longrightarrow \operatorname{Hom}(R(G) ; \mathbb{Q} / \mathbb{Z}) .
$$

The map $K_{0}\left(B G^{+} ; \mathbb{Q} / \mathbb{Z}\right) \rightarrow R(G) \otimes \mathbb{Q} / \mathbb{Z}$ defined by the composition

$$
\begin{align*}
& K_{0}\left(B G^{+} ; \mathbb{Q} / \mathbb{Z}\right) \xrightarrow{L} \\
& \quad \operatorname{Hom}\left(K^{0}\left(B G^{+}\right) ; \mathbb{Q} / \mathbb{Z}\right) \xrightarrow{\alpha^{*}} \operatorname{Hom}(R(G) ; \mathbb{Q} / \mathbb{Z}) \stackrel{L_{R}}{\longleftrightarrow} R(G) \otimes \mathbb{Q} / \mathbb{Z} \tag{2.3}
\end{align*}
$$

is easily seen to be the same as $\psi_{G}$ in (2.1). For simplicity we shall use (2.3) as definition for $\psi_{G}$ and take (2.1) as motivation.

## PROPOSITION 2.4.

(i) $\psi_{G}$ is injective.
(ii) For a p-group $G, \quad \psi_{G}: K_{0}\left(B G^{+} ; \mathbb{Q} / \mathbb{Z}_{(p)}\right) \rightarrow R(G) \otimes \mathbb{Q} / \mathbb{Z}_{(p)} \quad$ is an isomorphism.
(iii) $\psi_{G}$ is natural in $G$.

Proof. Observe first that $\psi_{G}$ factorizes through $\operatorname{Hom}_{c}\left(K^{0}\left(B G^{+}\right) ; \mathbb{Q} / \mathbb{Z}\right)$. Since $\alpha: R(G) \rightarrow K^{\prime 0}\left(B G^{+}\right)$is continuous, $R(G)$ having the $I$-adic and $K^{0}\left(B G^{+}\right)$the skeletal topology, ([2], §7) we obtain a map $\operatorname{Hom}_{c}\left(K^{0}\left(B G^{+}\right) ; \mathbb{Q} / \mathbb{Z}\right) \xrightarrow{\alpha^{*}} \operatorname{Hom}_{c}(R(G) ; \mathbb{Q} / \mathbb{Z})$ which is easily seen to be injective. Therefore the composition

$$
\begin{aligned}
& K_{0}\left(B G^{+} ; \mathbb{Q} / \mathbb{Z}\right) \xrightarrow[\cong]{L} \operatorname{Hom}_{c}\left(K^{0}\left(B G^{+}\right) ; \mathbb{Q} / \mathbb{Z}\right) \xrightarrow{\alpha^{*}} \operatorname{Hom}_{c}(R(G) ; \mathbb{Q} / \mathbb{Z}) \\
& \subset \operatorname{Hom}(R(G) ; \mathbb{Q} / \mathbb{Z}) \stackrel{L_{R}}{\leftrightarrows} R(G) \otimes \mathbb{Q} / \mathbb{Z}
\end{aligned}
$$

which is simply $\psi_{G}$, is injective.
For a $p$-group $G, I$-adic completion is the same as $p$-adic completion. This implies that the map $\operatorname{Hom}_{c}\left(K^{0}\left(B G^{+}\right) ; \mathbb{Q} / \mathbb{Z}_{(p)}\right) \rightarrow \operatorname{Hom}\left(R(G) ; \mathbb{Q} / \mathbb{Z}_{(p)}\right)$ is an isomorphism, hence $\psi_{G}$ must be an isomorphism after localizing at $(p)$.

The $\operatorname{map} \psi_{G}$ is characterised by the equation $\left\langle y, \psi_{G}(x)\right\rangle_{R}=\langle\alpha(y), x\rangle_{K}$, $y \in R(G)$. The naturality properties of $\psi_{G}$ then follow simply from corresponding properties of $\alpha$. Let $f: H \rightarrow G$ be a homomorphism of groups, $f^{*}: R(G) \rightarrow R(H)$ the induced map on representation rings and ind ${ }_{H}^{G}: R(H) \rightarrow R(G)$ the map generalizing the usual induction map for $H \rightarrow G$ an inclusion (see e.g. [19] 7.1.). Then

$$
\begin{aligned}
\left\langle y, \operatorname{ind}_{H}^{G} \psi_{H}(x)\right\rangle_{R} & =\left\langle f^{*}(y), \psi_{H}(x)\right\rangle_{R}=\left\langle\alpha\left(f^{*}(y)\right), x\right\rangle_{K}=\left\langle B f^{*}(\alpha(y)), x\right\rangle_{K} \\
& =\left\langle y, \psi_{G}\left(B f_{*}(x)\right)\right\rangle_{R}
\end{aligned}
$$

implies $\psi_{G}\left(B f_{*}(x)\right)=\operatorname{ind}_{H}^{G}\left(\psi_{H}(x)\right)$.
Similarly, if $f$ is an inclusion with tranfer $t: B G^{+} \rightarrow B H^{+}$we find $\psi_{H}(t(x))=$ $f^{*} \psi_{G}(x)$.

Remark 2.5. Let $i: *=B\{1\} \rightarrow B G$ denote the canonical map. Then $K_{0}(B G ; \mathbb{Q} / \mathbb{Z}) \cong \operatorname{coker}\left(\operatorname{ind}_{(1\}}^{G}: R(\{1\}) \otimes \mathbb{Q} / \mathbb{Z} \rightarrow R(G) \otimes \mathbb{Q} / \mathbb{Z}\right)$ which is simply $\bar{R}(G) \otimes \mathbb{Q} / \mathbb{Z}$, where $\bar{R}(G)=R(G) /(\mathrm{reg})$ and $\mathrm{reg}=\operatorname{ind}_{\{1\}}^{G}(1)$. We obtain the embedding $\psi: K_{1}(B G) \cong K_{0}(B G ; \mathbb{Q} / \mathbb{Z}) \rightarrow \bar{R}(G) \otimes \mathbb{Q} / \mathbb{Z}$ mentioned in the introduction. The relation of $\psi$ to the $G$-signature is then proved in [11] (see also [24]), where also a different proof of (2.4) may be found).

Adams operations $\psi^{i}$ on $R(G)$ may be defined by the character formula

$$
\begin{equation*}
\chi_{\psi^{\prime}(\rho)}(g)=\chi_{\rho}\left(g^{i}\right) \tag{2.6}
\end{equation*}
$$

where $g \in G, \rho \in R(G)$ and $\chi_{\rho}$ is the character of $\rho$. Define for $i \not \equiv 0(p)$ $\psi_{2 n}^{i}(\rho):=i^{-n} \psi^{i}$ on $R(G) \otimes \mathbb{Q} / \mathbb{Z}_{(p)}$. Then

LEMMA 2.7. For $i \neq 0(p),(|G|, i)=1$, the Adams operation $\psi_{2 n}^{i}$ commutes with $\psi_{G}: K_{0}\left(B G^{+} ; \mathbb{Q} / \mathbb{Z}_{(p)}\right) \rightarrow R(G) \otimes \mathbb{Q} / \mathbb{Z}_{(p)}$.

Proof. Let $c \psi_{0}^{i}$ be the operation which is adjoint to $\psi_{0}^{i}$ with respect to $\langle,\rangle_{K}:\left\langle c \psi_{0}^{i}(x), y\right\rangle_{K}=\left\langle x, \psi_{0}^{i}(y)\right\rangle_{K}$. It is easy to see that $c \psi_{0}^{i}=\psi_{0}^{1 / i}$. The formula $\left\langle\psi_{0}^{i}(\rho), \psi_{0}^{i}(\mu)\right\rangle_{R}=\langle\rho, \mu\rangle_{R}$ in $R(G)([19], 12.4)$ implies that $\psi_{0}^{1 / i}$ is adjoint to $\psi_{0}^{i}$ with respect to $\langle,\rangle_{R},(i,|G|)=1$. The well known property of Adams operations $\alpha \circ \psi^{i}=\psi^{i} \circ \alpha$ implies the result.

If $G$ is not a $p$-group, then $\alpha: R(G) \rightarrow K^{0}\left(B G^{+}\right)$has a non-trivial kernel. Dual to this $\psi_{G}$ has a non-trivial cokernel. To describe im $\left(\psi_{G}\right)$ we first introduce the following notation.

For a finite group $G$ let $G_{p}$ be a $p$-Sylow subgroup of $G$ and res: $R(G) \rightarrow$ $R\left(G_{p}\right)$, ind: $R\left(G_{p}\right) \rightarrow R(G)$ the restriction and induction map associated with $G_{p} \subset G$. Recall that every $x \in G$ may be written in a unique way $x=x_{p} \cdot x_{p}^{\prime}$ where $x_{p}$ has order a power of $p(=p$-element $)$ and the order of $x_{p}^{\prime}$ is prime to $p$ and $x_{p}$ and $x_{p}^{\prime}$ commute. Choose $k \in \mathbb{N}$ such that the $k$-th power map $g \rightarrow g^{k}$ on $G$ acts as the identity on $p$-elements and by $g^{k}=e$ for $g$ with order prime to $p$. Using the decomposition $x=x_{p} \cdot x_{p}^{\prime}$ above one easily sees that $\psi^{k}: R(G) \rightarrow R(G)$ is idempotent and res induces an isomorphism $\psi^{k}(R(G)) \rightarrow \mathrm{im}$ (res).

Let $t: K_{0}\left(B G^{+} ; \mathbb{Q} / \mathbb{Z}_{(p)}\right) \rightarrow K_{0}\left(B G_{p}^{+} ; \mathbb{Q} / \mathbb{Z}_{(p)}\right)$ denote the transfer associated to $G_{p} \subset G$. Since $k$ is prime to $p, t$ commutes with $\psi^{k}$. From the fact that $\psi^{k}=1$ on $R\left(G_{p}\right)$ and the injectivity of $t$ it follows that $\operatorname{im}\left(\psi_{G}: K_{0}\left(B G^{+} ; \mathbb{Q} / \mathbb{Z}_{(p)}\right) \rightarrow R(G) \otimes\right.$ $\left.\mathbb{Q} / \mathbb{Z}_{(p)}\right)$ is contained in $\psi^{k}(R(G)) \otimes \mathbb{Q} / \mathbb{Z}_{(p)}$. Let $N_{G}\left(G_{p}\right)$ be the normalizer of $G_{p}$ in $G$ and define $W:=N_{G}\left(G_{p}\right) / G_{p}$. Then $W$ acts on $R\left(G_{p}\right)$ and $K_{1}(B G)$ in the canonical way. Denote by $K l(G)$ the $\mathbb{C}$-vector space of $\mathbb{C}$-valued class functions on $G$ and by $K l_{p}(G)$ the subspace of $K l(G)$ consisting of class-functions vanishing outside the set of $p$-elements.

PROPOSITION 2.8. With the notation as above we have

$$
\begin{aligned}
K_{0}\left(B G^{+} ; \mathbb{Q} / \mathbb{Z}_{(p)}\right) & \cong \psi^{k}(R(G)) \otimes \mathbb{Q} / \mathbb{Z}_{(p)} \cong \frac{R(G)}{\operatorname{ker}(\text { res })} \otimes \mathbb{Q} / \mathbb{Z}_{(p)} \\
& \cong \operatorname{im}(\text { res }) \otimes \mathbb{Q} / \mathbb{Z}_{(p)}
\end{aligned}
$$

The last isomorphism describes $t\left(K_{0}\left(B G^{+} ; \mathbb{Q} / \mathbb{Z}_{(p)}\right)\right)$ as a direct summand in $K_{0}\left(B G_{p}^{+} ; \mathbb{Q} / \mathbb{Z}_{(p)}\right) \cong R\left(G_{p}\right) \otimes \mathbb{Q} / \mathbb{Z}_{(p)}$.

Proof. Consider the commutative diagram

Then ind $(\operatorname{res}(x))=x \cdot \operatorname{ind}(1)$. Now ind $(1)=|G| /\left|G_{p}\right|+z$ with $z \in I(G)$ and $|G| /\left|G_{p}\right| \equiv 0(p)$.

Claim. In $(R(G) / \operatorname{ker}($ res $)) \otimes \mathbb{Z} / p^{i}$ we have $z^{m}=0$ for $m$ large enough. To prove this claim, observe that it is enough to show res $\left(z^{m}\right)=\operatorname{res}(z)^{m}=0$ in $R\left(G_{p}\right) \otimes \mathbb{Z} / p^{i}$. But res $(z)^{m} \in I\left(G_{p}\right)^{m}$ and the elements in $I\left(G_{p}\right)^{m}$ are divisible by $p^{i}, m$ large enough, because for a $p$-group $I$-adic and $p$-adic topology coincide. Therefore multiplication by ind (1) on $(R(G) / \operatorname{ker}(\mathrm{res})) \otimes \mathbb{Z} / p^{i}$ is an isomorphism. Since this is true for every $i$, it is true in the limit. The commutativity of the following diagram then implies the proposition.

Observe that the discussion above also shows that im (res) $)_{(p)} \subset R\left(G_{p}\right)_{(p)}$ is a direct summand (that $\mathrm{im}(\mathrm{res}) \subset R\left(G_{p}\right)$ is the inclusion of a direct summand was first proved in [15] by applying Brauer's theorem).

In some cases one can describe im $\left(\psi_{G}\right)$ as the subgroup of elements invariant under $W=N_{G}\left(G_{p}\right) / G_{p}$.

PROPOSITION 2.9. Let $G_{p}$ be a p-Sylow subgroup of the finite group $G$ and assume that the following condition is satisfied: (c) If $x, y \in G_{p}$ are conjugate in $G$, there exists $g \in N_{G}\left(G_{p}\right)$ with $g x g^{-1}=y$. Then
(a) $\operatorname{im}(\mathrm{res})_{(p)}=R\left(G_{p}\right)_{(p)}^{W}$
(b) $K_{1}(B G)_{(p)}=K_{1}\left(B G_{p}\right)^{W}$.
(c) is satisfied, for example, if $G_{p}$ is a normal subgroup of $G$ or if $G_{p}$ is abelian (see (2.5) IV in [7]).

Proof. (a) We trivially have im (res) $\subset R\left(G_{p}\right)^{W}$. As observed in the proof of (2.8) im (res) $)_{(p)}$ is a direct summand in $R\left(G_{p}\right)_{(p)}$, hence also in $R\left(G_{p}\right)_{(p)}^{W}$. To see $\operatorname{im}(\mathrm{res})_{(p)}=R\left(G_{p}\right)_{(p)}^{W}$ it is therefore enough to show that im (res) and $R\left(G_{p}\right)^{W}$ have the same rank.

We identify $R(G) \otimes \mathbb{C}$ with $K l(G)$. The map res restricted to $K l_{p}(G) \subset K l(G)$ is still onto im $\left(\right.$ res $\left.\otimes 1_{\mathbb{C}}\right) \subset R\left(G_{p}\right) \otimes \mathbb{C}$. It is injective since every conjugacy class of a $p$-element in $G$ contains at least one element of $G_{p}$. We now show that the composition

$$
\begin{aligned}
& K l_{p}(G) \cong \operatorname{im}\left(\text { res } \otimes 1_{\mathbb{C}}\right)=\operatorname{im}(\text { res }) \otimes \mathbb{C} \subset R\left(G_{p}\right)_{(p)}^{W} \otimes \mathbb{C} \\
& \quad \subset\left(R\left(G_{p}\right) \otimes \mathbb{C}\right)^{W}=K l\left(G_{p}\right)^{W}
\end{aligned}
$$

is surjective. This then proves the assertion about the ranks of im (res) and $R\left(G_{p}\right)^{W}$ completing the proof of (a).

Let $f \in K l\left(G_{p}\right)^{W}$ be a class function on $G_{p}$ invariant under $W$. Define $F: G \rightarrow \mathbb{C}$ by $F(x)=0$ if $x$ is not a $p$-element and by $F(x):=f\left(g x g^{-1}\right)$ for a $p$-element $x$ where $g \in G$ is such that $g x g^{-1} \in G_{p}$. To see that $F$ is well defined, assume that $h \in G$ also satisfies $h x h^{-1} \in G_{p}$. Since $h x h^{-1} \in G_{p}$ and $g x g^{-1} \in G_{p}$ are conjugate in $G$, they are conjugate in $N_{G}\left(G_{p}\right)$ by (c). Therefore $f$ takes the same value on $h x h^{-1}$ and $g x g^{-1}$, hence $F$ is well defined. In the same way it follows that $F$ is a class function, which clearly restricts to $f$.

Part (b) is an immediate consequence of (a) by observing that $\psi_{G_{p}}$ carries the action of $W$ on $K_{0}\left(B G_{p}^{+} ; \mathbb{Q} / \mathbb{Z}_{(p)}\right)$ to the action of $W$ on $R\left(G_{p}\right) \otimes \mathbb{Q} / \mathbb{Z}_{(p)}$.

For reduction to cyclic subgroups we use

LEMMA 2.10. In $K_{0}\left(B G^{+} ; \mathbb{Q} / \mathbb{Z}\right)$ we have

$$
x=\sum_{A \subset G} B i_{A^{*}}\left(\alpha\left(\theta_{A}\right) \cap t_{A}\left(\frac{x}{|G|}\right)\right)
$$

where $A$ runs through all cyclic subgroups of $G, i_{A}: A \hookrightarrow G$ is the inclusion with transfer $t_{A}: K_{0}\left(B G^{+} ; \mathbb{Q} / \mathbb{Z}\right) \rightarrow K_{0}\left(B A^{+} ; \mathbb{Q} / \mathbb{Z}\right)$ and $\theta_{A} \in R(A)$ is the (virtual) representation whose character takes the value $|A|$ on group generators and is zero otherwise.

Proof. We deduce this from the corresponding formula in $R(G)$. In $R(G)$ we have $|G| \cdot y=\sum_{A \subset G} \operatorname{ind}_{A}^{G}\left(\theta_{A} \otimes \operatorname{res}_{A}(y)\right.$ ) (e.g. see [19]). Applying $\alpha: R(G) \rightarrow$
$K^{0}\left(B G^{+}\right)$to this gives

$$
|G| \cdot y=\sum_{A \subset G} t_{A}\left(\alpha\left(\theta_{A}\right) \cup B i_{A}^{*}(y)\right)
$$

for all $y \in \operatorname{im}(\alpha)$.
Since $\psi_{G}: K_{0}\left(B G^{+} ; \mathbb{Q} / \mathbb{Z}\right) \rightarrow R(G) \otimes \mathbb{Q} / \mathbb{Z}$ is injective, an element $x \in$ $K_{0}\left(B G^{+} ; \mathbb{Q} / \mathbb{Z}\right)$ is determined by the values of $\langle y, x\rangle_{K}$ for all $y \in \operatorname{im}(\alpha)$. Hence

$$
x=\sum_{A \subset G} B i_{A} \cdot\left(\alpha\left(\theta_{A}\right) \cap t_{A}\left(\frac{x}{|G|}\right)\right)
$$

is true if $\langle y, x\rangle_{K}$ is equal to

$$
\left\langle y, \sum_{A \subset G} B i_{A^{*}}\left(\alpha\left(\theta_{A}\right) \cap t_{A}\left(\frac{x}{|G|}\right)\right)\right\rangle_{K}
$$

for all $y \in \operatorname{im}(\alpha)$. But this follows from the formula above.

A main ingredient for the proof of theorem (4.4) is some knowledge of the skeletal filtration on $K_{1}(B G)$. We first handle the case $G$ cyclic and then reduce the general case to this using (2.10).

PROPOSITION 2.11. Let $p$ be a prime, $C=\mathbb{Z} / p^{a}$ and $x \in K_{1}(B C)$ be an element with $p^{b} \cdot x=0$. Then the skeletal filtration of $x$ is less than $2(p-$ 1) $p^{a-1}(a+b)$.

Proof. Well known properties of lens spaces translate by duality into
(a) $i_{*}: K_{0}\left(B C^{(2 m)} ; \mathbb{Q} / \mathbb{Z}_{(p)}\right) \rightarrow K_{0}\left(B C ; \mathbb{Q} / \mathbb{Z}_{(p)}\right)$ is injective and
(b) $i_{*}\left(K_{0}\left(B C^{(2 m)} ; \mathbb{Q} / \mathbb{Z}_{(p)}\right)=\left\{z \in K_{0}\left(B C ; \mathbb{Q} / \mathbb{Z}_{(p)}\right) \mid\left\langle(H-1)^{s} ; z\right\rangle_{K}=0\right.\right.$ for $s>$ $m\}$ (e.g. see [9]). Here $H \rightarrow B C$ is the Hopf line bundle, $H=\alpha(\lambda)$.
Now $K_{0}\left(B C^{+} ; \mathbb{Q} / \mathbb{Z}_{(p)}\right) \cong R(C) \otimes \mathbb{Q} / \mathbb{Z}_{(p)}$ is generated by elements $x$ of the form $x=\lambda^{i p^{r}} \cdot \mid p^{k}, i \neq 0(p), r<a$ and every element $x$ with $p^{b} x=0$ can be written as an integral linear combination of such elements with $k \leq b$. Let $x=\lambda^{i p^{r}} / p^{b}$, then $\left\langle H^{i}, x\right\rangle_{K}=1 / p^{b}$ if $j \equiv i p^{r} \bmod p^{a}$ and zero otherwise. Hence

$$
\left\langle(H-1)^{s}, x\right\rangle_{K}=\sum_{j \geq 0}(-1)^{j+s}\binom{s}{j}\left\langle H^{j}, x\right\rangle_{K}=\sum_{j \geq 0}(-1)^{i p^{a}+i p^{r}+s}\binom{s}{i p^{r}+j p^{a}} \cdot p^{-b}
$$

If $f(t)=\sum a_{k} t^{k}$ is a power series in $t$ and $u, v$ integers with $0 \leq u<v$ then

$$
a_{u} t^{u}+a_{u+v} t^{u+v}+a_{u+2 v} t^{u+2 v}+\cdots=\frac{1}{v} \sum_{k=0}^{v-1} \omega^{-k u} f\left(\omega^{k} t\right)
$$

where $\omega=e^{2 \pi i / v}$. We apply this with $v=p^{a}, u=i p^{r}, i \neq 0(p), r<a$ and $f(t)=(1-t)^{s}$. The coefficient of $t^{i p^{r}+j p^{a}}$ in $f(t)$ is

$$
(-1)^{i p^{a}+i p^{r}+s}\binom{s}{i p^{r}+j p^{a}}
$$

hence with $t=1$

$$
\sum_{j \geq 0}(-1)^{i p^{a+i} p^{r}+s}\binom{s}{i p^{r}+j p^{a}} p^{-b}=p^{-b-a} \cdot \sum_{k=0}^{p^{a}-1} \omega^{-k p^{r \cdot i}}\left(\omega^{k}-1\right)^{s}
$$

But $\left(\omega^{k}-1\right)^{p^{a-1}(p-1)}$ is divisible by $p$. This implies that for $s \geq p^{a-1}(p-1)(b+a)$ the Kronecker products $\left\langle(H-1)^{s}, \lambda^{i p^{\prime}} / p^{b}\right\rangle_{K}$ vanish.

COROLLARY 2.12. Let $G$ be a finite group with exponent $e=p^{a} \cdot m$, $(m, p)=1$ and order $|G|=p^{c} \cdot m^{\prime},\left(m^{\prime}, p\right)=1$. If $x \in K_{0}\left(B G ; \mathbb{Q} / \mathbb{Z}_{(p)}\right)$ is an element with $p^{b} \cdot x=0$ then the skeletal filtration of $x$ is less than $2(p-1) p^{a-1}(b+$ $c+1$ ).

Proof. Consider the element $\theta_{A}$ defined in (2.10). Let $A=\mathbb{Z} / p^{r}, B=\mathbb{Z} / p$ and $\operatorname{pr}: A \rightarrow B$ the reduction map. Then, as is easy to see, we have $\theta_{A}=\operatorname{pr}^{*}(p-$ $\left.\operatorname{reg}_{A}\right) \cdot p^{r-1}$ which implies that $\theta_{A}$ is divisible by $p^{r-1}$. Using this and (2.10) we can estimate the skeletal filtration of $\alpha\left(\theta_{A}\right) \cap t_{A}(x /|G|)$ by (2.11).

Remark 2.13. A slightly better estimate for the skeletal filtration of an element of order $p^{b}$ may be obtained as follows:

$$
\begin{align*}
& \text { If } p^{b} \cdot x=0 \text { in } K_{1}(B C), C=\mathbb{Z} / p^{a} \text {, then } x \in \operatorname{im}\left(K_{1}\left(B C^{(2 m)}\right) \rightarrow K_{1}(B C)\right) \\
& \text { for } m \geq(p-1) p^{a-1}(b+1) . \tag{2.14}
\end{align*}
$$

Since we shall use this only in the examples we give only the main steps for the argument and refer to [11] for more details. The first step is to show that ( $1-\lambda^{i}$ ) for $i \neq 0(p)$ is invertible in $\bar{R}(C) \otimes \mathbb{Z}[1 / p]$ where $\bar{R}(C)=R(C) /\left(\mathrm{reg}_{C}\right)$. Hence, for $a_{i} \equiv 0(p), 1 / \prod_{i=1}^{m}\left(1-\lambda^{a_{1}}\right)$ is a well defined element in $K_{1}(B C) \cong \bar{R}(C) \otimes$
$\mathbb{Q} / \mathbb{Z}_{(p)}$. It is not hard to show that the skeletal filtration of such an element is at most $2 m$. The formula

$$
\theta_{A} \otimes \frac{x}{p^{a+c}}=\left(\theta_{A} \otimes x\right) /\left(\prod_{\substack{j=1 \\ j \neq 0(p)}}^{p^{r-1}}\left(1-\lambda^{j}\right)^{a+c}\right)
$$

for $x \in I(A)$ and $A=\mathbb{Z} / p^{r} \subset C$ is proved by comparing characters on both sides. Since $\theta_{A}$ is divisible by $p^{r-1}$, this equation shows that the skeletal filtration of

$$
x_{A}:=\alpha\left(\theta_{A} / p^{r-1}\right) \cap t_{A}\left(\frac{x}{p^{a+b-r+1}}\right) \text { for } x \in I(C)
$$

$A=\mathbb{Z} / p^{r} \subset C$ does not exceed $2(p-1) p^{r-1}(a+b-r+1)$. By (2.10) we have $x / p^{a}=\sum_{A} B i_{A^{*}}\left(x_{A}\right)$ with $A$ running through the cyclic subgroups of $C$. Hence $x \in \operatorname{im}\left(K_{0}\left(B C^{(2 m)} ; \mathbb{Q} / \mathbb{Z}_{(p)}\right) \rightarrow K_{0}\left(B C ; \mathbb{Q} / \mathbb{Z}_{(p)}\right)\right.$ for $m \geq \max \left\{(p-1) p^{r-1}(a+b-\right.$ $r+1) \mid 1 \leq r \leq a\}=(p-1) p^{a-1}(b+1)$.

If we use this bound in the proof for (2.12) we obtain $2(p-1) p^{a-1}(b+c-$ $a+1)$ as an upper bound for the skeletal filtration of an element of order $p^{b}$ in $K_{0}\left(B G ; \mathbb{Q} / \mathbb{Z}_{(p)}\right)$.

The last topic we have to discuss for the proof of theorem (4.4) is the kernel of the inclusion map $K_{1}\left(B G^{(m)}\right) \xrightarrow{i_{*}} K_{1}(B G)$. We need

PROPOSITION 2.15. Let $G$ be a finite group and $m \in \mathbb{N}$. Then there exists $r=r(m, G) \in \mathbb{N}$ such that $K_{0}\left(B G^{(m+r)} ; \mathbb{Q} / \mathbb{Z}\right) \xrightarrow{i_{*}} K_{0}(B G ; \mathbb{Q} / \mathbb{Z})$ is injective on $\operatorname{im}\left(K_{0}\left(B G^{(m)} ; \mathbb{Q} / \mathbb{Z}\right) \xrightarrow{j_{*}} K_{0}\left(B G^{(m+r)} ; \mathbb{Q} / \mathbb{Z}\right)\right)$.

This is essentially a statement about the Atiyah-Hirzebruch spectral sequence for the $K$-theory of $B G$. It is true for every $C W$-complex $X$ with $H^{i}(X ; \mathbb{Z})$ finite for all $i$. In the special case $X=B G$ much more is true, namely there exists $r(G) \in \mathbb{N}$ working for all $m$. This means simply that the Atiyah-Hirzebruch spectral sequence for the $K$-groups of $B G$ collapses after finitely many steps, despite $B G$ being an infinite complex. For $G=\mathbb{F}_{p}^{n}$, an elementary abelian group, this is stated in [2], there is only one non-zero differential $d_{2 p-1}$. I learned the fact and the proof that the Atiyah-Hirzebruch spectral sequence for $K^{0}(B G)$ satisfies $d_{r}=0$ for $r \geq r_{0}(G)$ from M. Hopkins. Later on I found out, that this result is already known [23]. We shall work with the weaker version (2.15).

To compute differentials in the Atiyah-Hirzebruch spectral sequence seems to be simpler in cohomology, so we turn to the dual statements. Using (2.2) we deduce $(2.15)$ from the following two propositions.

PROPOSITION 2.16. Let $X$ be an $C W$-complex with $H^{i}(X ; \mathbb{Z})$ finite for all $i$ and $m \in \mathbb{N}$. Then there exists $r_{0}=r_{0}(X, m) \in \mathbb{N}$ such that in the Atiyah-Hirzebruch spectral sequence for $K^{n}(X)$ we have $d_{r}^{p, q}=0$ for $r \geq r_{0}$ and all $p \leq m$.

Proof. This follows trivially from the fact that the $E_{2}$-term consists of finite groups.

PROPOSITION 2.17. Suppose that in the Atiyah-Hirzebruch spectral sequence for $K^{n}(X)$ we have $d_{r}^{p, n-p}=0$ for $r \geq r_{0}$ and all $p \leq m$. Then every $x \in K^{n}\left(X^{(m)}\right)$ which lifts to $K^{n}\left(X^{\left(m+r_{0}-1\right)}\right)$ lifts to $K^{n}(X)$.

Proof. We use the exact couple

$$
\left.\begin{array}{lc}
E_{1}^{s, q}=K^{s+q}\left(X^{(s)}, X^{(s-1)}\right) & K^{*}\left(X^{(s-1)}\right) \stackrel{i}{\longleftarrow} K^{*}\left(X^{(s)}\right) \\
D_{1}^{s, q}=K^{s+q}\left(X^{(s)}\right) & \ddots \ddots
\end{array}\right)
$$

Consider

We first show: If $x \in K^{n}\left(X^{(m)}\right)$ has a lift to an element $x^{\prime} \in K^{n}\left(X^{(m+r)}\right), r \geq r_{0}-1$, then it has a lift to $K^{n}\left(X^{(m+r+1)}\right)$.

Let $s$ be the exact filtration of $x$, i.e. $i^{m-s}(x) \neq 0$ in $K^{*}\left(X^{(s)}\right)$ but $i^{m-s+1}(x)=0$ in $K^{n}\left(X^{(s-1)}\right)$. Then $i^{m-s}(x)=j(y)$ for some $y \in K^{n}\left(X^{(s)}, X^{(s-1)}\right)$. If $x^{\prime} \in$ $K^{n}\left(X^{(m+r)}\right)$ is not in $\operatorname{im}(i)$, then $\delta\left(x^{\prime}\right)=z \neq 0$ in $K^{n+1}\left(X^{(m+r+1)}, X^{(m+r)}\right)$. By definition $z \in B_{m+r-s+2}^{m+r+1, n-m-r}$. Now $\operatorname{im}\left(d_{k}\right)=B_{k+1} / B_{k}$ and since $d_{k}^{p, n-q}=0$ for $k \geq r_{0}, p \leq m$ and $m+r-s+2 \geq r+1$ we have $z \in B_{r+1}^{m+r+1, n-m-r}$. Hence there exists $x^{\prime \prime} \in K^{n}\left(X^{(m+r)}\right)$ with $\delta\left(x^{\prime \prime}\right)=z$ and $x^{\prime \prime} \in \operatorname{ker}\left(i^{r}\right)$. Therefore $x^{\prime}-x^{\prime \prime} \in$ $\operatorname{ker}(\delta)=\operatorname{im}(i)$. But $i^{r}\left(x^{\prime}-x^{\prime \prime}\right)=i^{r}\left(x^{\prime}\right)=x$, hence $x \in \operatorname{im}\left(i^{r+1}\right)$. We conclude: $x \in \lim K^{n}\left(X^{(m+n)}\right)$ and there exists an element $\bar{x} \in K^{n}(X)$ restricting to $x$.

## §3. Upper bounds on im ( $h_{K}$ )

Restrictions for elements in $K_{*}(X)$ to be stably spherical are given by Adams operations. The simplest way to handle these seems to be the following. Fix an odd prime $p$ and choose $l$ generating $\left(\mathbb{Z} / p^{2}\right)^{*}$. Recall that there exists a generalized homology theory $\mathrm{Ad}_{*}$ fitting into the long exact sequence

$$
\begin{equation*}
\rightarrow \operatorname{Ad}_{i}(X) \xrightarrow{D} K_{i}(X)_{(p)} \xrightarrow{y_{i}^{\prime}-1} K_{i}(X)_{(p)} \xrightarrow{\Delta} \operatorname{Ad}_{t-1}(X) \rightarrow \tag{3.1}
\end{equation*}
$$

Here $\psi_{i}^{l}$ denotes the stable $K$-theory operation induced by the Adams operation $\psi^{l}$. We have a similar sequence in cohomology.

The $K$-theory Hurewicz map $h_{K}$ factors through Ad-theory

$$
h_{K}: \pi_{n}^{s}(X)_{(p)} \xrightarrow{h_{A}} \operatorname{Ad}_{n}(X) \xrightarrow{D} K_{n}(X)_{(p)}
$$

and since $\psi_{n}^{\prime}-1$ vanishes on $\operatorname{im}\left(h_{K}\right), \operatorname{ker}\left(\psi_{n}^{\prime}-1\right)=D\left(\operatorname{Ad}_{n}(X)\right)$ is an upper bound for $\operatorname{im}\left(h_{K}\right)$. In the case $X=B G, G$ a finite group, we have $K_{0}(B G)=0$, so $\operatorname{ker}\left(\psi_{2 n-1}^{l}-1\right)=\operatorname{Ad}_{2 n-1}(B G)$ and the Ad-group itself gives the upper bound.

Now stable homotopy is a connected homology theory, therefore the Ad-theory Hurewicz map will factor through the connected version $A_{*}(X)$ of Ad-theory. For $X$ a $C W$-complex, connected Ad-theory may be defined by

$$
\begin{equation*}
A_{n}(X):=\operatorname{im}\left(\operatorname{Ad}_{n}\left(X^{n}\right) \rightarrow \operatorname{Ad}_{n}\left(X^{n+1}\right)\right) . \tag{3.2}
\end{equation*}
$$

Let $d: A_{n}(X) \rightarrow \operatorname{Ad}_{n}(X)$ denote the canonical map. In general $d$ is neither injective nor surjective and $A$-theory gives an even better bound for im ( $h_{K}$ ). But usually $A_{*}(X)$ is much harder to calculate than $\operatorname{Ad}_{*}(X)$. The following result is the only one of this chapter which is needed in the proof of theorem (4.4).

PROPOSITION 3.3. Let $G$ be a finite group, e the exponent of $G$ and $n \neq 0$. Then (i) $\operatorname{Ad}_{2 n}(B G)=0$, (ii) $\operatorname{Ad}_{2 n-1}(B G)$ is finite and (iii) $n \cdot e \cdot \operatorname{Ad}_{2 n-1}(B G)=$ 0.

Proof. First of all we may reduce to a $p$-group by the following standard transfer argument. Let $t$ be the transfer associated with the inclusion $i: G_{p} \rightarrow G$ of a $p$-Sylow subgroup of $G$. Since $\mathrm{Bi}_{*^{\circ}}{ }^{\circ} t$ induces multiplication with $|G| /\left|G_{p}\right|$ in ordinary homology, it follows that $\mathrm{Bi}_{*}{ }^{\circ} t$ is an isomorphism for any $p$-local homology theory. Hence $\operatorname{Ad}_{*}(B G)$ is a direct summand in $\operatorname{Ad}_{*}\left(B G_{p}\right)$ and $\mathrm{Bi}_{*}: \mathrm{Ad}_{*}\left(B G_{p}\right) \rightarrow \mathrm{Ad}_{*}(B G)$ is onto.

Let now $G$ be a $p$-group, $e$ the exponent of $G$ and $v_{p}(e)$ the power of $p$ in the prime factorization of $e$. Observe next that the Bockstein map $\beta: \operatorname{Ad}_{2 n}(B G ; \mathbb{Q} / \mathbb{Z}) \rightarrow \operatorname{Ad}_{2 n-1}(B G)$ is bijective and that

$$
\operatorname{Ad}_{2 n}(B G ; \mathbb{Q} / \mathbb{Z}) \cong \operatorname{ker}\left(\psi_{2 n}^{l}-1\right) \quad \text { on } \quad K_{2 n}\left(B G ; \mathbb{Q} / \mathbb{Z}_{(p)}\right)
$$

This is the same as $\operatorname{ker}\left(l^{-n} \psi_{0}^{l}-1\right)=\operatorname{ker}\left(\psi_{0}^{l}-l^{n}\right)$ on $K_{0}\left(B G ; \mathbb{Q} / \mathbb{Z}_{(p)}\right) \cong R(G) \otimes$ $\mathbb{Q} / \mathbb{Z}_{(p)}$. From (2.6) we see that $\psi_{0}^{s}$ is periodic in $s$ with period $e$. Since $l$ generates the $p$-adic units, it is easy to see that for $s \neq 0(p) \psi_{0}^{s}$ operates on $\operatorname{ker}\left(\psi_{0}^{l}-l^{n}\right) \subset$ $K_{0}\left(B G ; \mathbb{Q} / \mathbb{Z}_{(p)}\right)$ as multiplication by $s^{n}$. Let now $v=(p-1) \cdot e / p$, then $s^{v} \equiv 1$ $\bmod e$ and $\psi_{0}^{s^{v}}=\psi_{0}^{1}=\mathrm{id}$ on $K_{0}\left(B G ; \mathbb{Q} / \mathbb{Z}_{(p)}\right)$. Therefore

$$
\left(s^{v \cdot n}-1\right) \cdot \operatorname{ker}\left(\psi_{0}^{l}-l^{n}\right)=0
$$

But $\min \left\{v_{p}\left(s^{n v}-1\right) \mid s \neq 0(p)\right\}=v_{p}(n)+v_{p}(v)+1=v_{p}(e \cdot n)$. This proves (iii). Since $K_{0}\left(B G ; \mathbb{Q} / \mathbb{Z}_{(p)}\right)$ is a finite sum of copies of $\mathbb{Q} / \mathbb{Z}_{(p)}$ (ii) follows from (iii). The vanishing of $\operatorname{Ad}_{2 n}(B G) \cong \operatorname{Ad}_{2 n-1}(B G ; \mathbb{Q} / \mathbb{Z})$ is then implied by (ii) using (3.1).

We first deal with $\operatorname{Ad}_{*}(B G)$ for a $p$-group $G$. Let $G$ be a $p$-group with exponent $e$ and $\rho$ an irreducible representation of $G$. For $l$ with $(l,|G|)=1, \psi^{l}(\rho)$ is again irreducible (e.g. [19], 9.4). Hence $\psi^{l}$ acts as a permutation on the set $\operatorname{Irr}(G)$ of irreducible representations of $G$. Denote by $V_{i}=\left\{\rho_{1}^{(i)}, \rho_{2}^{(i)}, \ldots, \rho_{s_{t}}^{(i)}\right\}$, $i=0, \ldots, w$, the orbits of this action. By renumbering we may assume $\psi^{l} \rho_{(k)}^{(i)}=\rho_{(k+1)}^{(i)}, \quad k<s_{i}$, and $\psi^{l} \rho_{s_{t}}^{(i)}=\rho_{1}^{(i)}$. We also assume $\rho_{1}^{(0)}=1$, the trivial representation. For an orbit $V=\left\{\rho_{1}, \ldots, \rho_{s}\right\}$ of the action of $\psi^{l}$ on $\operatorname{Irr}(G)$ define

$$
\begin{equation*}
x_{n}(V):=\frac{1}{l^{n \cdot s}-1} \cdot \sum_{j=0}^{s-1} \psi_{2 n}^{\prime \prime}\left(\rho_{1}\right)=\frac{1}{l^{n s}-1} \sum_{j=0}^{s-1} l^{-n \cdot j} \cdot \rho_{j+1} \tag{3.4}
\end{equation*}
$$

as an element in $R(G) \otimes \mathbb{Q} / \mathbb{Z}_{(p)} \cong K_{2 n}\left(B G ; \mathbb{Q} / \mathbb{Z}_{(p)}\right)$.

LEMMA 3.5. $x_{n}(V) \in \operatorname{ker}\left(\psi_{2 n}^{l}-1\right)$

Proof. Because of $\psi_{2 n}^{l}=l^{-n} \psi_{0}^{l}$ we have $\psi_{2 n}^{l}{ }^{\circ} \psi_{2 n}^{l \prime}=\psi_{2 n}^{l l+1}$. Therefore

$$
\left(\psi_{2 n}^{l}-1\right)\left(x_{n}(V)\right)=\left(l^{-s n} \rho_{1}-\rho_{1}\right) /\left(l^{s n}-1\right) \equiv 0 \bmod \mathbb{Z}_{(p)}
$$

Note that the denominator $l^{n s}-1$ in $x_{n}(V)$ is maximal.

PROPOSITION 3.6. Let $G$ be a p-group. Denote by $V_{i}=\left\{\rho_{1}^{(i)}, \ldots, \rho_{s_{t}}^{(i)}\right\}$ $i=1, \ldots, w$ the orbits of the action of $\psi^{l}$ on the set of nontrivial irreducible representations of $G$. Then for $n \neq 0$

$$
\operatorname{Ad}_{2 n-1}(B G) \cong \bigoplus_{i=1}^{w}\left(\mathbb{Z}_{(p)} /\left(l^{n \cdot s_{1}}-1\right)\right) \cdot x_{n}\left(V_{i}\right)
$$

Proof. Let $x=\sum a_{i j} \rho_{j}^{(i)}$ be an element in $\operatorname{ker}\left(\psi_{2 n}^{l}-1\right) \cong \operatorname{Ad}_{2 n}(B G ; \mathbb{Q} / \mathbb{Z})$. Then $\psi_{2 n}^{l} x-x=\sum_{i, j}\left(a_{i j} \psi_{2 n}^{l}\left(\rho_{j}^{(i)}\right)-a_{i j} \rho_{j}^{(i)}\right)=0$ gives the congruences

$$
a_{i, j} l^{-n} \equiv a_{i, j+1} \quad \text { for } \quad j<s_{i} \quad \text { and } \quad a_{i, s_{l}} l^{-n} \equiv a_{i, 1} .
$$

These imply $\left(l^{-s n}-1\right) a_{1, j} \equiv 0 \bmod \mathbb{Z}_{(p)}$ showing that $x$ can be written as an integral linear combination of the elements $x_{n}\left(V_{i}\right)$.

Next we give two reformulations of (3.6) and prove that $\operatorname{Ad}_{2 n-1}(B G)$ has $w$ cyclic summands (not depending on $n$ ).

The numbers $w$ and $s_{i}$ are related to the rational representation ring of $G$. To see this, recall the following facts from representation theory (e.g. see [19]). Let $\xi$ be a primitive $e$-th root of unity. Then all representations of $G$ may be realized over $\mathbb{Q}(\xi)$. The Galois group $\Gamma=\operatorname{Gal}(\mathbb{Q}(\xi): \mathbb{Q})$ operates in the usual way on $R(G)$ via its operation on the character values. If $\sigma \in \Gamma$ satisfies $\sigma(\xi)=\xi^{t}$ then $\sigma(\rho)=\psi^{t}(\rho)$, hence Galois action and action by Adams operation are the same. If $G$ is a $p$-group with $p \neq 2$ then $\Gamma$ is cyclic and we may take $\psi^{l}$ as generator.

Denote by $R(G)^{\Gamma}$ the elements of $R(G)$ invariant under $\Gamma$. Then $R(G)^{\Gamma}$ consists of representations with rational characters and the rational representation ring $R_{\mathbb{Q}}(G)$ is contained in $R(G)^{\Gamma}$ as a subgroup of maximal rank. For a $p$-group, $p \neq 2$, they are actually the same since all Schur indices are 1 ([8], (10.14)). If $V=\left\{\rho_{1}, \ldots, \rho_{s}\right\}$ is an orbit of the action of $\left\langle\psi^{l}\right\rangle=\Gamma$, where $G$ is now a $p$-group, then $\rho=\rho_{1}+\rho_{2}+\cdots+\rho_{s}$ is an irreducible rational representation. Thus $s=\langle\rho, \rho\rangle_{R}$ and $w$ is the number of nontrivial irreducible rational representations. Hence

PROPOSITION 3.7. Let $G$ be a p-group. Then the number of orbits of the action of $\psi^{\prime}$ on $\operatorname{Irr}(G)$ is equal to the rank of $R_{\mathbb{Q}}(G)$ and the number $s$ of elements in an orbit $V=\left\{\rho_{1}, \ldots, \rho_{s}\right\}$ is $s=\langle\rho, \rho\rangle_{R}$ where $\rho=\rho_{1}+\rho_{2}+\cdots \rho_{s}$ is the rational representation corresponding to $V$.

There is still another description of the orbit set of $\Gamma$. The Galois group $\Gamma$ acts also on the set of conjugacy classes of $G$. If $g \in G$ and $\sigma \in \Gamma$ satisfies $\sigma(\xi)=\xi^{t}$,
then $\sigma(g)=g^{t}$ is well defined. This induces an action of $\Gamma$ on the set $C(G)=\left\{c_{1}, \ldots, c_{m}\right\}$ of conjugacy classes of $G$. Let $w_{i}=\left\{c_{1}^{(i)}, \ldots, c_{h_{1}}^{(i)}\right\}, i=$ $0, \ldots, r$, the orbits of this action, $c_{j}^{(i)} \in C(G)$, with the convention $c_{1}^{(0)}=\{1\}$. For a $p$-group $G$ we take $\psi^{l}$ as generator of $\Gamma$. We use this action for our final description of $\mathrm{Ad}_{2 n-1}(G)$.

THEOREM 3.8. Let $G$ be a p-group with exponent e. Denote by $w_{i}=$ $\left\{c_{1}^{(i)}, \ldots, c_{h_{1}}^{(i)}\right\}, i=0,1, \ldots, r$, the orbits of the action of the cyclic group $\left\langle\psi^{l}\right\rangle$ on conjugacy classes $c_{j}^{(i)}$ of $G$ induced by the $l$-th power map, $\psi^{l}(g)=g^{l}$ for $g \in c_{j}^{(i)}$. Let $c_{1}^{(0)}=\{1\}$ be the conjugacy class of 1 . Then, for $n \neq 0, \operatorname{Ad}_{2 n-1}(B G)$ has exactly $r$ cyclic summands of order $p^{v_{p}(n)+v_{p}\left(h_{1}\right)}+1, i=1, \ldots, r$. In particular $h_{i} \equiv 0(p-1)$ for $i>0, v_{p}\left(h_{i}\right) \leq v_{p}(e)$ and $h_{i}=s_{i}, w=r$ in (3.6).

Proof. Let $f_{j}^{(i)}$ be the class function on $G$ which is 1 on $c_{j}^{(i)}$ and zero otherwise. Clearly the $\Gamma$ set $X_{1}:=\left\{f_{j}^{(i)}\right\}$ is $\Gamma$-equivariantly isomorphic to the $\Gamma$ set $C(G)$. The $\Gamma$ set $X_{1}$ defines a complex permutation representation $W^{1}$ and the $\Gamma$ set $X_{2}$ consisting of the irreducible representations of $G$ defines another permutation representation $W^{2}$. Clearly $W^{1}=W^{2}=R(G) \otimes \mathbb{C}$ as complex vector spaces, but (2.6) shows that they are also the same as $\Gamma$-modules. To show that the two $\Gamma$ sets $X_{1}$ and $X_{2}$ are isomorphic $\Gamma$ sets, observe that it is enough to show that $X_{1}$ and $X_{2}$ define the same element in the Burnside ring $\Omega(\Gamma)$ of $\Gamma$. The map which associates to a $\Gamma$ set its permutation representation defines a canonical map $\Omega(\Gamma) \rightarrow R(\Gamma)$. As long as $\Gamma$ is cyclic this map is injective (e.g. [19]). Hence $X_{1}$ is isomprhic to $X_{2}$ as a $\Gamma$ set, in particular $r=w$ and $h_{i}=s_{i}$.

It remains to show $h_{i} \equiv 0(p-1)$ for $i>0$. For then $v_{p}\left(l^{n \cdot s_{1}}-1\right)=v_{p}(n)+$ $v_{p}\left(s_{i}\right)+1$ and the order of $x_{n}\left(w_{i}\right)$ is as stated. Let $w=\left\{c_{1}, \ldots, c_{s}\right\}$ be an orbit of the $\left\langle\psi^{l}\right\rangle$-action on $C(G)$ not containing 1 , and arranged in such a way that $\psi^{l} c_{i}=c_{i+1}, i<s$, and $\psi^{l} c_{s}=c_{1}$. If $c_{1}=\left\{h^{-1} g h \mid h \in G\right\}$ then $c_{i}=\left\{h^{-1} g^{\mu-1} h \mid h \in\right.$ $G\}$. For some $h_{0} \in G$ we thus have $g^{l s}=h_{0}^{-1} g h_{0}$. Induction shows that $h^{-1} g h=g^{a}$ implies $h^{-k} g h^{k}=g^{a^{k}}$. Let $p^{b}$ be the order of $h_{0}$ and $p^{c}$ the order of $g$, then $g^{\left(l^{s} p^{b}\right.}=h^{-p^{b}} g h^{p^{b}}=g$ and therefore $l^{s p^{b}} \equiv 1 \bmod p^{c}$. By the choice of $l$ this is only possible if $s \equiv 0(p-1)$.

COROLLARY 3.9. Let $G$ be an abelian p-group and I the family of cyclic subgroups of $G$ different from $\{1\}$. Then

$$
\left.\operatorname{Ad}_{2 n-1}(B G)=\bigoplus_{A \in I}\left(\mathbb{Z}_{(p)}\right)|A| \cdot n\right) .
$$

Proof. Study the orbit set of $\left\langle\psi^{\prime}\right\rangle$ on $C(G)=G$.

EXAMPLE 3.10. (a) $G=\mathbb{Z} / p^{a}, R\left(\mathbb{Z} / p^{a}\right)=\mathbb{Z}[\lambda] /\left(\lambda^{p^{a}}=1\right)$. The orbits of $\left\langle\psi^{l}\right\rangle$ are $v_{i}=\left\{\lambda^{p^{\prime} \cdot j} \mid j \neq 0(p)\right\}, i=0, \ldots, a-1$, with $s_{i}=(p-1) p^{a-i-1}$. We have

$$
x_{n}\left(v_{i}\right)=\left(\sum_{k=0}^{s_{i}-1} l^{-k \cdot n} \lambda^{p^{\prime k^{k}}}\right) / p^{a-i+v_{p}(n)}=\left(\sum_{\substack{j=1 \\ j \neq 0(p)}}^{p^{a-1}} j^{-n} \lambda^{p^{\prime \cdot} \cdot j}\right) / p^{a-i+v_{p}(n)}
$$

and

$$
\operatorname{Ad}_{2 n-1}\left(B \mathbb{Z} / p^{a}\right)=\bigoplus_{i=0}^{a-1}\left(\mathbb{Z} / p^{a-i+v_{p}(n)}\right) \cdot x_{n}\left(v_{i}\right)
$$

(b) $G=\mathbb{Z} / p \times \mathbb{Z} / p, \quad R(G)=R(\mathbb{Z} / p) \otimes R(\mathbb{Z} / p)$. The orbits are $v_{i}=\left\{\lambda^{j} \otimes\right.$ $\left.\lambda^{j \cdot i} \mid j=1, \ldots, p-1\right\}, i=0, \ldots, p-1$ and $v_{p}=\left\{1 \otimes \lambda^{j} \mid j=1, \ldots, p-1\right\}$. The elements

$$
x_{n}\left(v_{i}\right)=\left(\sum_{j=1}^{p-1} j^{-n} \lambda^{j} \otimes \lambda^{j \cdot i}\right) / p^{1+v_{p}(n)}, \quad i=0, \ldots, p-1
$$

and

$$
x_{n}\left(v_{p}\right)=\left(\sum_{j=1}^{p-1} j^{-n} \cdot 1 \otimes \lambda^{j}\right) / p^{1+v_{p}(n)} \quad \text { generate } \quad \operatorname{Ad}_{2 n-1}(B G) \cong \bigoplus_{j=0}^{p} \mathbb{Z} / p^{1+v_{p}(n)}
$$

(c) $G$ a non abelian group of order $p^{3}$. For simplicity let $p=3$. There are 2 non isomorphic groups $G_{1}=(\mathbb{Z} / 3 \times \mathbb{Z} / 3) \rtimes \mathbb{Z} / 3$ and $G_{2}=\mathbb{Z} / 9 \rtimes \mathbb{Z} / 3$. In both cases we have 5 orbits of length $p-1=2$. So

$$
\operatorname{Ad}_{2 n-1}\left(B G_{i}\right)=\stackrel{5}{j=1} \mathbb{Z} / 3^{1+v_{3}(n)} \quad \text { for } \quad i=1,2
$$

We now turn to an arbitrary finite group $G$ with exponent $m, e=v_{p}(m) \geq 1$ and $s(e):=(p-1) \cdot p^{e-1}$.

To describe elements in $\operatorname{Ad}_{2 n-1}(B G)$ we introduce the map

$$
\tau: R(G) \rightarrow R(G) \otimes \mathbb{Q} / \mathbb{Z}_{(p)}
$$

defined by

$$
\tau(x)=\left(\sum_{j=0}^{s(e)-1} \psi_{2 n}^{\prime \prime}(x)\right) /\left(l^{n \cdot s(e)}-1\right)
$$

We assume $l$ is chosen satisfying $(|G|, l)=1$.

LEMMA 3.11. If $G$ is a p-group with exponent $p^{e}$ then

$$
\operatorname{im}\left(\tau: R(G) \rightarrow R(G) \otimes \mathbb{Q} / \mathbb{Z}_{(p)}\right) \cong \operatorname{Ad}_{2 n}\left(B G^{+} ; \mathbb{Q} / \mathbb{Z}\right)
$$

Proof. Let $v=\left\{\rho_{1}, \ldots, \rho_{k}\right\}$ be an orbit of the action of $\psi^{l}$ on $\operatorname{Irr}(G)-\{1\}$. It suffices to show $\tau\left(\rho_{1}\right)=c \cdot x_{n}(v)$ for some $c \neq 0(p)$. Let $r=s(e) / k$ then

$$
\begin{aligned}
\tau\left(\rho_{1}\right) & =\left(\sum_{a=0}^{r-1} l^{-n k a}\left(\rho_{1}+l^{-n} \rho_{2}+\cdots+l^{-n(k-1)} \rho_{k}\right)\right) /\left(l^{n \cdot s(e)}-1\right) \\
& =\frac{l^{n \cdot k}-1}{l^{n \cdot s(e)}-1} \cdot\left(\sum_{a=0}^{r-1} l^{-n k a}\right) \cdot x_{n}(v)=\frac{l^{n \cdot k}-1}{l^{n \cdot s(e)}-1} \frac{1-l^{-n k r}}{1-l^{n k}} \cdot x_{n}(v)
\end{aligned}
$$

Recall the notation introduced preceding (2.8). Let $G_{p} \subset G$ be a $p$-Sylow subgroup of $G$ and $k \in \mathbb{N}$ as in (2.8). For $x \in R(G)$ the element $\tau(x) \in R(G) \otimes$ $\mathbb{Q} / \mathbb{Z}_{(p)}$ is not necessarily in $\operatorname{ker}\left(\psi_{2 n}^{l}-1\right)$, but this is true for $x \in \operatorname{im}$ (ind: $R\left(G_{p}\right) \rightarrow$ $R(G)$ ) or $x \in \psi^{k}(R(G))$ as we shall see now.

PROPOSITION 3.12. (a) $\tau($ im (ind $)) \cong \psi_{G}\left(\operatorname{Ad}_{2 n}\left(B G^{+} ; \mathbb{Q} / \mathbb{Z}\right)\right)$
(b) $\tau\left(\psi^{k}(R(G))\right) \cong \psi_{G}\left(\operatorname{Ad}_{2 n}\left(B G^{+} ; \mathbb{Q} / \mathbb{Z}\right)\right)$ in $R(G) \otimes \mathbb{Q} / \mathbb{Z}_{(p)}$.

Proof. Consider the following commutative diagram

Because of $(|G|, l)=1 \operatorname{ind}_{G_{p}}^{G}$ and $\psi^{l}$ will commute, so the left hand square in (3.13) is commutative. This shows $\left(\psi_{2 n}^{l}-1\right)(\tau(x))=0$ for $x \in \operatorname{im}$ (ind). The facts that $\mathrm{Bi}_{*}$ and $\psi_{G_{p}}$ are onto in (3.13) then imply (a) by (3.11). Part (b) is proved similarly.

EXAMPLE 3.14. Let $G=\Sigma_{m}$ be the symmetric group on $m$ symbols. Then $R\left(\Sigma_{m}\right)=R_{\mathbb{Q}}\left(\Sigma_{m}\right)([19], 13.1)$ hence $\psi^{l}=1$ on $R\left(\Sigma_{m}\right)$. Therefore

$$
\tau(x)=x \cdot\left(\sum_{j=0}^{s(e)-1} l^{-n j}\right) /\left(l^{n \cdot s(e)}-1\right)=x \cdot \frac{\left(1-l^{-n \cdot s(e)}\right)}{\left(1-l^{-n}\right) \cdot\left(l^{n \cdot s(e)}-1\right)}
$$

and $\operatorname{Ad}_{2 n-1}\left(B \Sigma_{m}\right)$ is zero if $n \neq 0(p-1)$ and a direct sum of cyclic groups of order $p^{1+v_{p}(n)}$ if $n \equiv 0(p-1), n \neq 0$.

The following proposition describes $\mathrm{Ad}_{2 n-1}\left(B G^{+}\right)$as a subgroup of $\operatorname{Ad}_{2 n-1}\left(B G_{p}^{+}\right)$.

PROPOSITION 3.15. The map $\mathrm{Bi}_{*}: \operatorname{Ad}_{2 n-1}\left(B G_{p}^{+}\right) \rightarrow \operatorname{Ad}_{2 n-1}\left(B G^{+}\right)$restricted to $\tau(\mathrm{im}(\mathrm{res})) \subset \operatorname{Ad}_{2 n}\left(B G_{p}^{+} ; \mathbb{Q} / \mathbb{Z}\right) \cong \operatorname{Ad}_{2 n-1}\left(B G_{p}^{+}\right)$is bijective.

Proof. Let $x \in \operatorname{Ad}_{2 n}\left(B G^{+} ; \mathbb{Q} / \mathbb{Z}\right)$ be given. By (3.12) (a) there exists $x_{1}$ with $\tau\left(\operatorname{ind}\left(x_{1}\right)\right)=x$. Choose $i$ with $p^{i} \cdot \operatorname{Ad}_{2 n-1}\left(B G_{p}^{+}\right)=0$. The proof of (2.8) then shows that we can choose $x_{1}$ in im (res) $\bmod p^{i}$. Hence there is $x_{2} \in \operatorname{im}$ (res) with $\tau\left(\operatorname{ind}\left(x_{2}\right)\right)=x$. But then $\mathrm{Bi}_{*}\left(\tau\left(x_{2}\right)\right)=x$ and $\mathrm{Bi}_{*}$ is onto.

Assume that we have $\tau(\operatorname{res}(z)) \in \operatorname{ker}\left(\mathrm{Bi}_{*}\right)$ for $z \in R(G)$. Since $\psi^{k}(z)$ and $z(k$ as in (2.8)) have the same image under res, we may assume $z \in \psi^{k}(R(G))$. But then $\tau(z) \in R(G) \otimes \mathbb{Q} / \mathbb{Z}_{(p)}$ is in $\operatorname{ker}\left(\psi_{2 n}^{l}-1\right)=\operatorname{Ad}_{2 n}\left(B G^{+} ; \mathbb{Q} / \mathbb{Z}\right)$ and $t(\tau(z))=$ $\tau(\operatorname{res}(z))$ in $\mathrm{Ad}_{2 n}\left(B G_{p}^{+} ; \mathbb{Q} / \mathbb{Z}\right)$ by naturality. Since $\mathrm{Bi}_{*}{ }^{\circ} t$ is bijective it follows $\tau(\operatorname{res}(z))=0$ and $\mathrm{Bi}_{*}$ is injective.

We now turn to the problem of determining the group structure of $\operatorname{Ad}_{2 n-1}(B G)$. Let $C_{p}(G)$ be the set of conjugacy classes of $p$-elements in the finite group $G$ and $\Gamma$ the finite cyclic group generated by the action of the $l$-th power map on $C_{p}(G)$. Denote by $B_{i}=\left\{C_{1}^{(i)}, C_{2}^{(i)}, \ldots, C_{h_{1}}^{(i)}\right\}, i=0,1, \ldots, r$, $C_{j}^{(i)} \in C_{p}(G)$, the orbits with respect to this action with the convention that $B_{0}$ is the orbit of the unit element of $G$.

The class functions dual to $C_{j}^{(i)}$ give a basis of $K l_{p}(G)$, the vector space of class functions vanishing outside the $p$-elements of $G$. Since the action of $\psi^{l}$ on $K l_{p}(G)$ corresponds to the action of the $l$-th power map on $C_{p}(G)$ we see that $K l_{p}(G)$ is a permutation representation of the finite cyclic group $\left\langle\psi^{l}\right\rangle$ generated by $\psi^{l}$. Consider now

$$
P:=\operatorname{im}(\mathrm{res})_{(p)} \subset R\left(G_{p}\right)_{(p)}
$$

A direct generalization of (3.8) from $p$-groups to arbitrary groups is possible if one knows that $P$ is a $\left\langle\psi^{l}\right\rangle$-permutation representation. This is true at least rationally: In the proof of (2.9) we have seen that $P \otimes \mathbb{C}$ and $K l_{p}(G)$ are isomorphic as $\left\langle\psi^{l}\right\rangle$-modules. Hence $P \otimes \mathbb{C}$ is a $\left\langle\psi^{l}\right\rangle$-permutation representation. Since $r: R_{\mathbb{Q}}\left(\left\langle\psi^{l}\right\rangle\right) \rightarrow R_{\mathbb{C}}\left(\left\langle\psi^{l}\right\rangle\right)$ is injective, $K l_{p}(G), P \otimes \mathbb{C}$ both are in im $(r)$ and $K l_{p}(G)$ may be realized as a permutation representation over $\mathbb{Z}$ it follows that $P \otimes \mathbb{Q}$ is a $\left\langle\psi^{l}\right\rangle$-permutation representation.

Whether or not $P$ itself is a $\left\langle\psi^{l}\right\rangle$-permutation-representation seems to be unknown in general. In (3.17) we shall describe some cases where this is true.

PROPOSITION 3.16. Let $G$ be a finite group with p-Sylow subgroup $G_{p}$. Assume that $P=\operatorname{im}\left(\mathrm{res}: R(G) \rightarrow R\left(G_{p}\right)\right)_{(p)}$ is a $\left\langle\psi^{l}\right\rangle$-permutation representation. Then

$$
\operatorname{Ad}_{2 n-1}(B G) \cong \bigoplus_{i=1}^{r} \mathbb{Z}_{(p)} /\left(l^{n \cdot h_{i}}-1\right)
$$

Proof. By (3.15) we have $\mathrm{Ad}_{2 n}\left(B G^{+} ; \mathbb{Q} / \mathbb{Z}\right) \cong \tau(P)$ in $R\left(G_{p}\right) \otimes \mathbb{Q} / \mathbb{Z}_{(p)}$. Let $S$ denote the $\left\langle\psi^{l}\right\rangle$-set defining the $\left\langle\psi^{l}\right\rangle$-permutation representation $P$. As in the case of a $p$-group we obtain a description of the group structure of $\tau(P)$ by number and length of the $\left\langle\psi^{l}\right\rangle$-orbits on $S$. The fact that the $\left\langle\psi^{l}\right\rangle$-permutation representation $P \otimes \mathbb{C}$ and $K l_{p}(G)$ are $\left\langle\psi^{l}\right\rangle$-isomorphic implies that the $\left\langle\psi^{l}\right\rangle$-sets $S$ and $C_{p}(G)$ have the same orbit structure (see proof of (3.8)).

The assumptions of (3.16) are clearly satisfied if the $l$-th power map acts trivially on $C_{p}(G)$, for then $P$ has to be the trivial permutation representation. We may apply (3.16) also in the situation of (2.9):

PROPOSITION 3.17. If $P=\operatorname{im}(\mathrm{res})_{(p)}=R\left(G_{p}\right)_{(p)}^{W}$ then $P$ is $a\left\langle\psi^{\prime}\right\rangle$ permutation representation.

Proof. The actions of $W=N_{G}\left(G_{p}\right) / G_{p}$ and $\left\langle\psi^{l}\right\rangle$ on $R\left(G_{p}\right)$ commute and we have an induced action of $\left\langle\psi^{l}\right\rangle$ on $R\left(G_{p}\right)_{(p)}^{W}$. Define $s: R\left(G_{p}\right)_{(p)} \rightarrow R\left(G_{p}\right)_{(p)}^{W}$ by

$$
s(x):=\frac{1}{|W|} \sum_{\sigma \in W} \sigma(x) .
$$

Then $s$ is $\left\langle\psi^{l}\right\rangle$-equivariant. It is easy to see that if $\lambda \in R\left(G_{p}\right)$ is irreducible and $\sigma \in W$ then $\sigma(\lambda)$ is irreducible too. Hence $W$ operates on the set $\operatorname{Irr}\left(G_{p}\right)$. Under the map $s$ the $W$-orbits on $\operatorname{Irr}\left(G_{p}\right)$ define a basis of $R\left(G_{p}\right)_{(p)}^{W}$ and since $\left\langle\psi^{l}\right\rangle$ maps $W$-orbits to $W$-orbits we see that $R\left(G_{p}\right)_{(p)}^{W}$ is a permutation representation of the group $\left\langle\psi^{l}\right\rangle$.

EXAMPLE 3.18. Let $G=D_{10}=\mathbb{Z} / 10 \rtimes \mathbb{Z} / 2$ be the dihedral group of order 20 and $p=5$. There are two conjugacy classes of elements of order 5 in $D_{10}$, which are permutated by $\psi^{l}$. Hence we have one orbit of length 2 , so

$$
\operatorname{Ad}_{2 n-1}\left(B D_{10}\right)=\mathbb{Z}_{(5)} /\left(l^{2 n}-1\right)=\left\{\begin{array}{cl}
\mathbb{Z} / 5^{1+v_{s}(n)} & n \equiv 0(2) \\
0 & n \equiv 1(2)
\end{array}\right.
$$

Remark. The number of cyclic summands in $\mathrm{Ad}_{2 n-1}(B G)$ depends only on the residue class of $n \bmod (p-1)$. This is easily seen by introducing $\bmod p$ coefficients and observing that $\psi_{2 n}^{l} \equiv \psi_{2 m}^{\prime} \bmod p$ if $n \equiv m \bmod (p-1)$. Using this and the fact that $P \otimes \mathbb{Q}$ is a $\left\langle\psi^{\prime}\right\rangle$-permutation representation one can still prove: The groups
have the same order and the same number of cyclic summands. We omit the details.

Remark. Comparison of the exact sequences for $\operatorname{Ad}_{n}(B G ; \mathbb{Q} / \mathbb{Z})$ and $\mathrm{Ad}_{n}^{G}\left(S^{0} ; \mathbb{Q} / \mathbb{Z}\right)$ (here $\mathrm{Ad}^{G}$ denotes $G$-equivariant Ad-theory), gives the relation between $\operatorname{Ad}_{*}(B G)$ and $\operatorname{Ad}_{*}^{G}\left(S^{0}\right)_{(p)}$

$$
\begin{aligned}
& \rightarrow \operatorname{Ad}_{n}^{G i}\left(S^{0} ; \mathbb{Q} / \mathbb{Z}_{(p)}\right) \rightarrow K_{n}^{(i}\left(S^{0} ; \mathbb{Q} / \mathbb{Z}_{(p)}\right) \xrightarrow{\psi_{n}^{\prime}-1} K_{n}^{(i}\left(S^{0} ; \mathbb{Q} / \mathbb{Z}_{(p)}\right) \rightarrow \operatorname{Ad}_{n-1}^{(i)}\left(S^{\prime \prime} ; \mathbb{Q} / \mathbb{Z}_{(p)}\right) \rightarrow \\
& \uparrow_{\bar{\psi}_{c}} \quad \uparrow_{\psi_{c}} \\
& \rightarrow \mathrm{Ad}_{n}\left(B G^{+} ; \mathbb{Q} / \mathbb{Z}_{(p)}\right) \rightarrow K_{n}\left(B G^{+} ; \mathbb{Q} / \mathbb{Z}_{(p)}\right) \xrightarrow{y_{n}^{\prime}-1} K_{n}\left(B G^{+} ; \mathbb{Q} / \mathbb{Z}_{(p)}\right) \rightarrow \operatorname{Ad}_{n-1}\left(B G^{+} ; \mathbb{Q} / \mathbb{x}_{1},\right.
\end{aligned}
$$

In particular, if $G$ is a $p$-group, then $\bar{\psi}_{G}$ is an isomorphism. We close this chapter with a short discussion of $\operatorname{Ad}^{*}(B G)$.

For a finite group $G$, Rector [17] studied $K \mathbb{F}_{q}^{*}(B G)$, where $K \mathbb{F}_{q}^{*}$ is the algebraic $K$-theory associated with the finite field $\mathbb{F}_{q}$. If we choose the number $l$ in the definition of $A^{*}$ to be a prime power then $K \mathbb{F}_{l}^{*}(X)_{(p)} \cong A^{*}(X)$. Let $R_{\mathbb{F}_{4}}(G)$ denote the Grothendieck group of finitely generated $\mathbb{F}_{q}[G]$-modules, $I$ the augmentation ideal of $R_{\mathrm{F}_{4}}(G)$ and $R_{\mathrm{F}_{4}}(G)^{\wedge}$ the $I$-adic completion of $R_{\nabla_{4}}(G)$. Rector proved an analogue of Atiyah's theorem [2], $K \mathbb{F}_{q}^{0}\left(B G^{+}\right) \cong R_{\mathbb{F}_{q}}(G)^{\wedge}$ and $K \mathbb{F}_{q}^{2 i}(B G)=0$ for $i<0$. For $i<0$ and $\mathbb{F}_{s}$ a splitting field of $G$ he gave a description of $K \mathbb{F}_{q}^{2 i+1}\left(B G^{+}\right)$as the kernel of $\psi^{q}-1$ on $R_{\mathbb{F}}(G)^{\wedge} \otimes K \mathbb{F}_{s}^{2 i+1}\left(S^{\prime}\right)$.

Since we are mainly interested in $\operatorname{Ad}_{*}(B G)$ we have given a description of $\mathrm{Ad}_{*}(B G)$ which is independent of [17]. The two approaches may be related by the following universal coefficient formula for Ad-theory which is proved in [14].

PROPOSITION 3.19. Let $X$ be a CW-complex and $R$ an abelian group. Then the following sequence is exact

$$
0 \rightarrow \operatorname{Ext}\left(\operatorname{Ad}_{i-1}(X) ; R_{(p)}\right) \rightarrow \operatorname{Ad}^{i+1}(X ; R) \rightarrow \operatorname{Hom}\left(\operatorname{Ad}_{i}(X) ; R_{(p)}\right) \rightarrow 0 .
$$

COROLLARY 3.20. Let $G$ be a finite group and $n \neq 0$. Then

$$
\operatorname{Ad}^{1+2 n}(B G) \cong \operatorname{Ad}_{2 n-1}(B G) .
$$

## §4. Lower bounds for im $\left(h_{K}\right)$ and the proof of theorem (4.4)

We shall use an extension of the classical $J$-homomorphism to $A^{0}(X)$

$$
j_{A}: A^{0}(X) \rightarrow \pi_{s}^{0}(X)_{(p)}
$$

to construct elements in $\pi_{*}^{s}(B G)$. For other applications of this method see e.g. [4], [5]. The extension $j_{A}$ of $J$ results from a solution of the Adams conjecture and may be constructed as follows (in the complex case): Let BSF denote the classifying space for spherical fibrations, $\mathbf{J}$ the fibre of $\psi^{l}-1$ and $J: U \rightarrow S F$ the classical (complex) $J$-map. Then $A^{0}(X)=[X, \mathrm{~J}]$ and $[X, S F] \cong \pi_{s}^{0}(X)$ for connected $X$. A solution of the Adams conjecture provides us with a map $\alpha$ in the following commutative diagram of classifying spaces (localised at $p$ ):

Then $j_{A}$ is the induced map between fibres and $J=j_{A} \circ \Delta$. It is then proved in [22] that $h_{A} \circ j_{A}$ is a bijection. Observe that $j_{A}$ induces a map $A^{0}(X) \rightarrow \pi_{s}^{0}(X)_{(p)}$ only for $X$ a space, not for a spectrum. So there is no corresponding map in $A$-homology.

Using $S$-duality we can still draw the following conclusion from the existence of $j_{A}$. For a $C W$-complex $X$ with finite $k$-skeleton $X^{(k)}$ let $D\left(X^{(k)}\right)$ be an $S$-dual of $X^{(k)}$.

PROPOSITION 4.1. Suppose $x \in \operatorname{Ad}_{n}(X)$ is in im $\left(\operatorname{Ad}_{n}\left(X^{(k)}\right) \rightarrow \operatorname{Ad}_{n}(X)\right)$ and there exists a space $Y$ such that $\Sigma^{n} D\left(X^{(k)}\right)_{(p)}$ and $Y_{(p)}$ are homotopy equivalent. Then $x$ is in $\operatorname{im}\left(h_{A}: \pi_{n}^{s}(X)_{(p)} \rightarrow \operatorname{Ad}_{n}(X)\right)$.

Proof. Consider the following commutative diagram

where the isomorphisms are defined by $S$-duality. Since $\Sigma^{n} D\left(X^{(k)}\right)_{(p)} \simeq Y_{(p)}$ is a space and $\operatorname{Ad}^{0}(Y)=A^{0}(Y)$, the existence of $j_{A}$ implies that $h_{A}: \pi_{n}^{s}\left(X^{(k)}\right)_{(p)} \rightarrow$ $\operatorname{Ad}_{n}\left(X^{(k)}\right)$, is onto. Hence the result.

Theorem 1 of [6] states that a $2 n-2$ connected spectrum of finite type (localized at $p \neq 2$ ) with dimension less than $2 n p-1$ can be realized by a space. If we apply this to desuspend the stable dual $D\left(B G^{(2 m)}\right)$ we obtain

COROLLARY 4.2. If $x \in \operatorname{Ad}_{2 n-1}(B G)$ is in im $\left(\operatorname{Ad}_{2 n-1}\left(B G^{(2 m)}\right) \rightarrow\right.$ $\operatorname{Ad}_{2 n-1}(B G)$ ) with $p m \leq n(p-1)$ then $x \in \operatorname{im}\left(h_{A}\right)$.

This is the lower bound for $\operatorname{im}\left(h_{A}\right)$ which we shall use. Examples show that usually this type of lower bound gives only a proper subgroup of im $\left(h_{A}\right)$. This is also true in the case of $B G$ in a certain dimension range. But as we shall see now, for $n$ sufficiently large, the skeletal filtration of the elements in $\operatorname{Ad}_{2 n-1}(B G)$ becomes small enough so that (4.2) applies. We first prove the main result in the special case of a cyclic group $G=\mathbb{Z} / p^{a}$. Let $c_{0}(a) \in \mathbb{N}$ be minimal with $p^{c} \geq p^{a}(2 a+c)$ for $c \geq c_{0}(a)$.

THEOREM 4.3. Let $p$ be an odd prime, $C$ be the cyclic group of order $p^{a}$ and $n_{0}=p^{a}\left(2 a+c_{0}(a)\right)$. Then, for $n \geq n_{0}$,

$$
h_{A}: \pi_{2 n-1}^{s}(B C) \rightarrow \operatorname{Ad}_{2 n-1}(B C) \text { is onto. }
$$

In particular, for $n \geq n_{0}$, im $\left(h_{K}: \pi_{2 n-1}^{s}(B C) \rightarrow K_{1}(B C)\right)$ is the subgroup

$$
\operatorname{Ad}_{2 n-1}(B C)=\operatorname{ker}\left(\psi_{2 n-1}^{I}-1\right) .
$$

Proof. Let $x$ be an element in $\operatorname{Ad}_{2 n-1}(B C)$. Then $v_{p}(|D(x)|) \leq a+v_{p}(n)$ by (3.3) and this implies $D(x)=i_{*}\left(x_{1}\right)$ for some $x_{1} \in K_{1}\left(B C^{(2 m)}\right)$ with $m \leq(p-1) p^{a-1}\left(2 a+v_{p}(n)\right)$. Since $i_{*}: K_{1}\left(B C^{(2 m)}\right) \rightarrow K_{1}(B C)$ is injective we have $\left(\psi_{2 n-1}^{l}-1\right)\left(x_{1}\right)=0$, hence there exists $x_{2} \in \operatorname{Ad}_{2 n-1}\left(B C^{(2 m)}\right)$ with $x_{1}=D\left(x_{2}\right)$. If $p m \leq n(p-1)$ we have $x \in \operatorname{im}\left(h_{A}\right)$ by (4.2). This is satisfied if $p^{a}\left(2 a+v_{p}(n)\right) \leqslant n$. Write $n=p^{c} \cdot n^{\prime}, \quad\left(n^{\prime}, p\right)=1$. If $c \geq c_{0}(a)$ then $n=p^{c} n^{\prime} \geq p^{c} \geq p^{a}(2 a+c)=$ $p^{a}\left(2 a+v_{p}(n)\right)$ by the definition of $c_{0}(a)$. If $c<c_{0}(a)$ then $n \geq n_{0}=p^{a}(2 a+$ $\left.c_{0}(a)\right) \geq p^{a}\left(2 a+v_{p}(n)\right)$ by the definition of $n_{0}$. Hence $n \geq n_{0}$ implies $p^{a}(2 a+$ $\left.v_{p}(n)\right) \leq n$ finishing the proof.

Remarks. (a) Combining (2.14) with (5.4) gives a slight improvement for $n_{0}: c_{0}^{\prime}(a)=\min \left\{c \mid p^{c} \geq p^{a}(a+c)\right\}$ and $n_{0}^{\prime}=p^{a}\left(a+c_{0}^{\prime}(a)\right)$. (b) The exact skeletal filtration of the elements of order $p$ in $\operatorname{Ad}_{2 n-1}(B C)$ is known, see [13].

## We now prove

THEOREM 4.4. Let $G$ be a finite group and $p$ an odd prime. Then there exists $n_{0}(G) \in \mathbb{N}$ such that for $n \geq n_{0}(G)$ the image of the Hurewicz map

$$
h_{K}: \pi_{2 n-1}^{s}(B G)_{(p)} \rightarrow K_{1}(B G)_{(p)}
$$

is the subgroup $\operatorname{Ad}_{2 n-1}(B G)=\operatorname{ker}\left(\psi_{2 n-1}^{l}-1\right)$.
Proof. Let $y \in \operatorname{Ad}_{2 n}(B G ; \mathbb{Q} / \mathbb{Z})$ be given. Then $x=D(y) \in \operatorname{ker}\left(\psi_{2 n}^{l}-1\right) \subset$ $K_{2 n}\left(B G ; \mathbb{Q} / \mathbb{Z}_{(p)}\right)$ satisfies $v_{p}(|x|) \leq c+v_{p}(n)$ for some $c \in \mathbb{N}$ by (3.3). Consider

$$
x_{A}:=\alpha\left(\theta_{A}\right) \cap t_{A}\left(\frac{x}{|G|}\right) \in K_{2 n}\left(B A^{+} ; \mathbb{Q} / \mathbb{Z}_{(p)}\right)
$$

for a cyclic subgroup $A=\mathbb{Z} / p^{a}$ of $G$. Then $v_{p}\left(\left|x_{A}\right|\right) \leq c^{\prime}+v_{p}(n)$ and we have $x_{A}=i_{*}\left(x_{A}^{\prime}\right) \quad$ for $\quad$ some $\quad x_{A}^{\prime} \in K_{2 n}\left(B A^{(2 m)+} ; \mathbb{Q} / \mathbb{Z}_{(p)}\right) \quad$ with $\quad m=m(a) \leq(p-$ 1) $p^{a-1} \cdot\left(a+c^{\prime}+v_{p}(n)\right)$ by (2.11). Now $x_{A}^{\prime}$ may not be in $\operatorname{ker}\left(\psi_{2 n}^{\prime}-1\right)$. But $|G| \cdot x_{A}$ is, since $\left.\psi_{2 n}^{l}\left(\alpha\left(\theta_{A}\right) \cap t_{A}(x)\right)=\psi_{0}^{l}\left(\alpha\left(\theta_{A}\right)\right) \cap \psi_{2 n}^{l}\left(t_{A}(x)\right)\right)=\alpha\left(\theta_{A}\right) \cap t_{A}(x)$. Let $\bar{m}=\max \left\{m(a) \mid \mathbb{Z} / p^{a}<G\right\}$. Then $x^{\prime}:=\sum_{A} \mathrm{Bi}_{A^{*}}\left(x_{A}^{\prime}\right) \in K_{0}\left(B G^{(2 \bar{m})} ; \mathbb{Q} / \mathbb{Z}_{(p)}\right)$ maps to $x$ under the inclusion $i: B G^{(2 m)} \rightarrow B G$.

Since $i_{*}: K_{0}\left(B G^{(2 \bar{m})} ; \mathbb{Q} / \mathbb{Z}_{(p)}\right) \rightarrow K_{0}(B G ; \mathbb{Q} / \mathbb{Z})$ is in general not injective we only know ( $\left.\psi_{2 n}^{l}-1\right)\left(x^{\prime}\right) \in \operatorname{ker}\left(i_{*}\right)$. But we know ( $\left.\psi_{2 n}^{l}-1\right)\left(x^{\prime}\right)$ is at most of order $|G|$ since $\left(\psi_{2 n}^{l}-1\right)\left(|G| \cdot x_{A}\right)=0$ as observed above. The elements $z \in$ $K_{0}\left(B G ; \mathbb{Q} / \mathbb{Z}_{(p)}\right) \quad$ with $\quad|G| \cdot z=0 \quad$ are $\quad$ all $\quad$ in $\quad i m\left(K_{0}\left(B G^{\left(m_{1}\right)} ; \mathbb{Q} / \mathbb{Z}_{(p)}\right) \rightarrow\right.$ $\left.K_{0}\left(B G ; \mathbb{Q} / \mathbb{Z}_{(p)}\right)\right)$ by (2.12), $m_{1}$ depending only on $|G|$. By (2.15) we can find $r=r\left(m_{1}, G\right)$ such that $i_{*}: K_{0}\left(B G^{\left(m_{1}+r\right)} ; \mathbb{Q} / \mathbb{Z}_{(p)}\right) \rightarrow K_{0}\left(B G ; \mathbb{Q} / \mathbb{Z}_{(p)}\right)$ is injective on $\operatorname{im}\left(K_{0}\left(B G^{\left(m_{1}\right)} ; \mathbb{Q} / \mathbb{Z}_{(p)}\right) \rightarrow K_{0}\left(B G^{\left(m_{1}+r\right)} ; \mathbb{Q} / \mathbb{Z}_{(p)}\right)\right.$. We conclude that, letting $m_{2}:=$ $\max \left\{2 \bar{m}, m_{1}+r\right\}$, the element $i_{*}\left(x^{\prime}\right) \in K_{0}\left(B G^{\left(m_{2}\right)} ; \mathbb{Q} / \mathbb{Z}_{(p)}\right)$ is in $\operatorname{ker}\left(\psi_{2 n}^{l}-1\right)$. Hence $y \in \operatorname{im}\left(\operatorname{Ad}_{2 n}\left(B G^{\left(m_{2}\right)} ; \mathbb{Q} / \mathbb{Z}\right) \rightarrow \operatorname{Ad}_{2 n}(B G ; \mathbb{Q} / \mathbb{Z})\right)$.

Now $m_{2}$ depends linearly on $v_{p}(n)$, so we may argue as in the proof of (4.3) that there exists $n_{0}(G)$ such that for $n \geq n_{0}(G)$ the element $y$ is in im $\left(h_{A}\right)$ by (4.2), proving the theorem.

Remark 4.5. (a) The only constant going into $n_{0}(G)$ in (4.4) which is not known in general is the constant $r\left(m_{1}, G\right)$ coming in by using (2.15).
(b) For $G=(\mathbb{Z} / p)^{k}$, an elementary abelian group, we know $r_{0}(G) \leq 2 p$ by [2].
(c) for $G=\left(\mathbb{Z} / p^{b}\right)^{k}, k \geq 2$, the length of the non-trivial differentials in the Atiyah-Hirzebruch spectral sequence for $K^{0}(B G)$ grows with $b$. It can be made arbitrarily large by increasing $b$.
(d) The case $\left(\mathbb{Z} / p^{b}\right)^{2}$ is special, since there are no non-trivial differentials starting in $E_{2}^{p,-p}$ with $p=0(2)$, hence $r\left(m_{1}, G\right)=1$ in this case.
(e) Closely related to this is the case of a $p$-group with $p$-rank at most 2 (the $p$-rank of a $p$-group is the rank of a maximal elementary abelian subgroup). If $p \geq 5$, it is known [21] that $H^{\text {even }}(B G ; \mathbb{Z})$ is generated by Chern classes of representations, implying that $H^{\text {even }}(B G ; \mathbb{Z})$ consists of permanent cycles. So we have $r\left(m_{1}, G\right)=1$ for those groups too. The groups of example (3.10c) belong to this class of groups (even for $p=3$ ).
(f) By using the fact that the Atiyah-Hirzebruch spectral sequence for $K_{*}(B G)$ collapses after finitely many steps [23], one can easily prove that there exists a constant $n_{1}(G) \geq n_{0}(G)$ such that for $n \geq n_{1}(G)$ $h_{A}: \pi_{2 n-1}^{s}(B G) \rightarrow \operatorname{Ad}_{2 n-1}(B G)$ is a split surjection.

For $G$ abelian we can avoid the use of (2.15) and thus obtain an explicit estimate for $n_{0}(G)$ as follows.

We first prepare a lemma true for arbitrary finite $G$. Recall the situation in (3.12). Let $G_{p} \stackrel{i}{\hookrightarrow} G$ be a $p$-Sylow subgroup of $G, R_{p}=\operatorname{im}$ (ind: $R\left(G_{p}\right) \rightarrow R(G)$ ), $E=$ exponent of $G, e=v_{p}(E)$ and $s(e)=(p-1) p^{e-1}$, then $\psi^{p(c)}=1$ in $R\left(G_{p}\right)$ and therefore in $K_{1}(B G)(2.8)$. By (3.12) every element in $\operatorname{Ad}_{2 n}(B G ; \mathbb{Q} / \mathbb{Z})$ is given by $\tau(x)=\sum_{i=0}^{s(e)-1} \psi_{2 n}^{r}(x) /\left(l^{n s(e)}-1\right)$ for some $x \in R_{p}$. Denote by $i: Y(m) \rightarrow B G$ the inclusion of a subcomplex contained in $B G^{(2 m)}$.

LEMMA 4.6. With the notations above, let $x^{\prime} \in K_{0}\left(Y(m) ; \mathbb{Q} / \mathbb{Z}_{(p)}\right)$ be an element with $i_{*}\left(x^{\prime}\right)=x /\left(l^{n \cdot s(e)}-1\right)$ for $x \in R_{p}$. Assume that the following conditions are satisfied:
(a) $m p \leq n(p-1)$
(b) $\psi_{0}^{\text {ple }}=1$ on $K_{0}\left(Y(2 m) ; \mathbb{Q} / \mathbb{Z}_{(p)}\right)$
(c) $\left(l^{n \cdot s(e)}-1\right) x^{\prime}=0$

Then $\tau(x) \in \operatorname{im}\left(h_{A}\right)$.
Proof. We show that $x^{\prime \prime}:=\sum_{i=0}^{s(e)-1} \psi_{2 n}^{\prime \prime}\left(x^{\prime}\right)$ is in $\operatorname{ker}\left(\psi_{2 n}^{\prime}-1\right)$. We have $\left(\psi_{2 n}^{\prime}-1\right)\left(x^{\prime \prime}\right)=x^{\prime}-\psi_{2 n}^{p(c)}\left(x^{\prime}\right)=x^{\prime}\left(1-l^{-n s(e)}\right)=0$ by (b) and (c). Then $\tau(x)=$ $i_{*}\left(x^{\prime \prime}\right)$ is in im ( $h_{A}$ ) by (a) and (4.2).

Next we show how to satisfy (b) and (c) for $G$ abelian. Let $G$ be an abelian $p$-group.

LEMMA 4.7. Let $G=\prod_{i=1}^{c} \mathbb{Z} / p^{a_{i}}$ be an abelian $p$-group, $p \neq 2$, and set $e=\max \left\{a_{i}\right\}, \quad s(e)=(p-1) p^{e-1}, \quad X_{i}=B \mathbb{Z} / p^{a_{i}}, \quad Y=\bigwedge_{i=1}^{c} X_{i} \quad$ and $\quad Y(m):=$ $\bigwedge_{i=1}^{c} X_{i}^{(2 m)}$ with inclusion $i_{Y}: Y(m) \rightarrow Y$. Then
(a) $\operatorname{ker}\left(i_{Y^{*}}\right) \subset K_{1}(Y(m))$ is a direct summand and
(b) $\psi_{0}^{(s(e)}=1$ on $K_{0}(Y(m) ; \mathbb{Q} / \mathbb{Z})$

Proof. (a) we use the Künneth sequence [3] to compute the $K$-theory of $Y(m)$. From [3] it follows that there exists a natural short exact sequence

$$
0 \rightarrow K_{*}(X) \otimes K_{*}(Y) \xrightarrow{\mu} K_{*}(X \wedge Y) \xrightarrow{\gamma} K_{*}(X) * K_{*}(Y) \rightarrow 0
$$

with $\gamma$ of degree -1 . Moreover, this sequence splits (unnaturally), e.g. see [16]. We now use induction on $c$. Consider the commutative diagram

$$
0 \longrightarrow K_{1}\left(X^{(2 m)}\right) \otimes K_{0}(Y(m))
$$

$$
\begin{aligned}
& \xrightarrow{\mu} K_{1}\left(X^{(2 m)} \wedge Y(m)\right) \xrightarrow{\gamma} K_{1}\left(X^{(2 m)}\right) * K_{1}(Y(m)) \longrightarrow 0
\end{aligned}
$$

with $X=B \mathbb{Z} / p^{a}$ and we have used $K_{0}\left(X^{(2 m)}\right)=0$. The case $c=1,2$ are trivially true since $i_{Y^{*}}$ is injective, starting the induction. By induction assumption the kernel of $i_{Y^{*}}$ splits off, hence the kernel of $\left(i_{X^{*}}\right) *\left(i_{Y^{*}}\right)$. The splitting of the Künneth sequence then proves the induction step.

To prove (b) we prove the dual statement and use the following fact, proved in [16] p. 267

$$
\begin{align*}
& K^{*}(X \wedge Y) \text { is generated by elements of the form } x_{0} \wedge y_{0}, \beta_{k}\left(x_{k} \wedge y_{k}\right) \\
& \text { for } k \geq 1 \text {, where } x_{0} \in K^{*}(X), \quad y_{0} \in K^{*}(Y), \quad x_{k} \in K^{*}(X ; \mathbb{Z} / k), \quad y_{k} \in \\
& K^{*}(Y ; \mathbb{Z} / k) \text {, } \tag{4.8}
\end{align*}
$$

$\beta_{k}: K^{*}(X \wedge Y ; \mathbb{Z} / k) \rightarrow K^{*}(X \wedge Y)$ is the Bockstein map and $\wedge, \wedge_{k}$ denote the product maps for $K^{*}()$ and $K^{*}(-; \mathbb{Z} / k)$.

We again use induction on $c$ and the Künneth sequence. The exact sequence

$$
0 \rightarrow K^{*}\left(X^{(2 m)} ; \mathbb{Z} / p^{k}\right) \rightarrow K^{*}\left(X^{(2 m)}\right) \xrightarrow{p^{k}} K^{*}\left(X^{(2 m)}\right) \rightarrow K^{*}\left(X^{(2 m)} ; \mathbb{Z} / p^{k}\right) \rightarrow 0
$$

shows $\psi^{5(c)}=1$ to be true on $K^{*}\left(X^{(2 m)} ; \mathbb{Z} / p^{k}\right)$ since it is true on $K^{*}(X)$ and $i_{X}^{*}: K^{*}(X) \rightarrow K^{*}\left(X^{(2 m)}\right)$ is onto. Let $M_{r}$ denote the Moore spectrum for $\mathbb{Z} / p^{r}$. Then $K^{i}\left(X ; \mathbb{Z} / p^{r}\right)=K^{i+1}\left(X \wedge M_{r}\right)$ and $K^{i}\left(X \wedge M_{k} ; \mathbb{Z} / p^{r}\right)=K^{i+1}\left(X \wedge M_{k} \wedge M_{r}\right)$. Since $p \neq 2$ we have a splitting $M_{k} \wedge M_{r} \simeq M_{t} \vee \Sigma M_{t}$ where $t=\min (k, r)$. This shows $\psi^{s(c)}=1$ on $K^{*}\left(X \wedge M_{p} ; \mathbb{Z} / p^{r}\right)$. Inductively we get the statement for
$K^{*}(Y(m))$ and $K^{*}\left(Y(m) ; \mathbb{Z} / p^{r}\right)$ using (4.8) and the facts that $\beta_{k}$ and $\wedge_{k}$ commute with $\psi^{l}$.

It is now rather clear how (4.6) and (4.7) give an estimate for $n_{0}(G), G$ abelian.

COROLLARY 4.9. $G=\prod_{i=1}^{c} \mathbb{Z} / p^{a_{i}}, \quad e=\max \left\{a_{i}\right\}, \quad b=v_{p}(|G|), \quad d_{0}=\min$ $\left\{d \mid p^{d} \geq p^{e} \cdot c(e+b+1+d)\right\}, \quad n_{1}(G):=p^{e} \cdot c\left(e+b+1+d_{0}\right)$. Then, for $n \geq$ $n_{1}(G), h_{A}: \pi_{2 n-1}^{s}(B G) \rightarrow \operatorname{Ad}_{2 n-1}(B G)$ is onto.

Proof. Let $x \in R(G)$ be given. Then $x / p^{e+v_{p}(n)}$ comes from the $2 m$-skeleton with $m \leq(p-1) p^{e-1}\left(e+v_{p}(n)+b+1\right)$ by (2.12). We have

$$
B G^{(2 m)} \subset \bigwedge_{i=1}^{c}\left(B \mathbb{Z} / p^{a_{i}^{+}}\right)^{(2 m)}=Y(m) \subset B G^{(2 m c)} .
$$

By (4.6) $\tau(x) \in \operatorname{im}\left(h_{A}\right)$ provided $m \cdot c p \leq(p-1) n$. As in the proof for (4.3) we find that this is the case for $n \geq n_{1}$ with $n_{1}$ as above.

Remark. (4.8) gives only a rough estimate for $n_{0}(G)$. It can be improved using splittings of $B G$ and the better estimates (2.13).

EXAMPLES 4.10. (a) As first example we treat $G=\mathbb{Z} / p \times \mathbb{Z} / p, p$ an odd prime. Recall the description of $\operatorname{Ad}_{*}(B G)$ from (3.10b). For $G=\mathbb{Z} / p \times \mathbb{Z} / p$, $n \neq 0, \mathrm{Ad}_{2 n-1}(B G)=\bigoplus_{i=0}^{p} \mathbb{Z} / p^{1+v_{p}(n)}$ is generated by

$$
x_{n}\left(v_{i}\right)=\left(\sum_{j=0}^{p-1} j^{-n} \lambda^{j} \otimes \lambda^{j \cdot i}\right) / p^{1+v_{p}(n)}, \quad i=0, \ldots, p-1,
$$

and

$$
x_{n}\left(v_{p}\right)=\left(\sum_{j=0}^{p-1} j^{-n} 1 \otimes \lambda^{j}\right) / p^{1+v_{p}(n)}
$$

We need to know the skeletal filtration on $\operatorname{Ad}_{2 n-1}(B G)$, which we abreviate by SF. Observe first that if we know $\operatorname{SF}\left(x_{n}\left(v_{1}\right)\right)$ we know $\operatorname{SF}\left(x_{n}\left(v_{i}\right)\right)$ for $i=$ $1, \ldots, p-1$. The reason is that the map induced by multiplication by $i$ in the second factor maps $x_{n}\left(v_{1}\right)$ to $x_{n}\left(v_{i}\right)$. Therefore if $x_{n}\left(v_{1}\right)$ is in im $\left(h_{A}\right)$, then $h_{A}$ is onto. Of course, for a given $n$, appropriate linear combinations of $x_{n}\left(v_{i}\right)$ 's have a smaller skeletal filtration and may be in im $\left(h_{A}\right)$ whereas $x_{n}\left(v_{1}\right)$ may not.

We use (2.10) to estimate $\operatorname{SF}\left(x_{n}\left(v_{1}\right)\right)$. Let $C$ denote a cyclic subgroup of $G$ and $i_{c}$ the inclusion. Then

$$
x_{c}:=\alpha\left(\theta_{c}\right) \cap t_{c}\left(x_{n}\left(v_{1}\right)\right) / p^{2} \in K_{0}\left(B C^{+} ; \mathbb{Q} / \mathbb{Z}\right)
$$

has order at most $p^{3+v_{p}(n)}$. In the case $C \cong \mathbb{Z} / p$ the skeletal filtration of an element of order $p^{t}$ does not exceed $2(p-1) \cdot t$. Since $\operatorname{SF}\left(\theta_{c}\right)=2(p-1)$ (for $C \cong \mathbb{Z} / p)$, we find $\operatorname{SF}\left(x_{c}\right) \leq 2(p-1)\left(2+v_{p}(n)\right)$ and thus $\operatorname{SF}(x) \leq 2(p-1)(2+$ $v_{p}(n)$ ).

Also, $K_{0}\left(B G^{(2 m+1)} ; \mathbb{Q} / \mathbb{Z}\right) \rightarrow K_{0}(B G ; \mathbb{Q} / \mathbb{Z})$ is injective on $\operatorname{im}\left(K_{0}\left(B G^{(2 m)} ;\right.\right.$ $\mathbb{Q} / \mathbb{Z}) \rightarrow K_{0}\left(B G^{(2 m+1)} ; \mathbb{Q} / \mathbb{Z}\right)$ or simpler $K_{1}\left(B G^{(2 m)}\right) \rightarrow K_{1}(B G)$ is injective in this special case. By (4.2) we know $x \in \operatorname{im}\left(h_{A}\right)$ provided $n \geq p\left(2+v_{p}(n)\right)$. This is the case for $n \geq 2 p+1$ if $p \geq 5(n \geq 3 p+1$ if $p=3)$. On the other hand, since $h_{A}: \pi_{k}^{s}\left(S^{0}\right)_{(p)} \rightarrow A_{k}\left(S^{0}\right) \quad$ in bijective for $k<2\left(p^{2}-p-1\right)$, we have $h_{A}: \pi_{2 n-1}^{s}(B G) \rightarrow A_{2 n-1}(B G)$ is onto for $n \leq p^{2}-p$. For $p \geq 5$ all dimensions are covered; for $p=3$ one needs an extra check by hand for $n=3 p$, which is not covered by (4.2). We have proved:

PROPOSITION 4.11. Let $p$ be an odd prime and $G=\mathbb{Z} / p \times \mathbb{Z} / p$. Then for $n>2 p \operatorname{im}\left(h_{K}: \pi_{2 n-1}^{s}(B G) \rightarrow K_{1}(B G)\right)$ is isomorphic to $\operatorname{Ad}_{2 n-1}(B G)=\operatorname{ker}\left(\psi^{I}-\right.$ 1). For $n \leq 2 p$ im ( $h_{K}$ ) is isomorphic to $d\left(A_{2 n-1}(B G)\right)$.
(b) Since the range where $h_{A}: \pi_{n}^{s}(X)_{(p)} \rightarrow A_{n}(X)$ is bijective depends on $p$, the argument above easily extends to $G=(\mathbb{Z} / p)^{b}, b \leq p-1$. Only the case $n=p^{2}, b=p-1$, is not covered by (3.2) and has to be handled by a different method.

PROPOSITION 4.12. Let $p>3$ be a prime and $G=(\mathbb{Z} / p)^{b}, b \leq(p-1)$. Then for $n>p^{2}-2 p \operatorname{im}\left(h_{K}: \pi_{2 n-1}^{s}(B G) \rightarrow K_{1}(B G)\right) \quad$ is isomorphic to $\operatorname{Ad}_{2 n-1}(B G)$ and for $n \leq p^{2}-2 p$ to $d\left(A_{2 n-1}(B G)\right)$.
(c) Note that the evaluation of $(H-1)^{p-1} \otimes(H-1)^{p-1}$ on $x_{n}\left(v_{1}\right)$ (for $\left.v_{p}(n)=0, \quad n \equiv 0(p-1)\right)$ shows $\operatorname{SF}\left(x_{n}\left(v_{1}\right) \geq 2(p-1) \cdot 2\right.$ (in $\operatorname{Ad}_{2 n}(B(\mathbb{Z} / p \times$ $\mathbb{Z} / p) ; \mathbb{Q} / \mathbb{Z})$, if $n=2(p-1)$ the skeletal filtration of $\beta x_{n}\left(v_{1}\right) \in \operatorname{Ad}_{2 n-1}(B(\mathbb{Z} / p \times$ $\mathbb{Z} / p)$ ) may be smaller). This shows that $d\left(A_{2 n-1}(B G)\right)$ and $\operatorname{Ad}_{2 n-1}(B G)$ actually may differ in low dimensions.

EXAMPLE. $p=3, \quad G=\mathbb{Z} / 3 \times \mathbb{Z} / 3$, $\operatorname{coker}\left(d: A_{2 n-1}(B G) \rightarrow \operatorname{Ad}_{2 n-1}(B G)\right) \cong$ $\mathbb{Z} / 3 \oplus \mathbb{Z} / 3$ for $n=1,3$ and $\mathbb{Z} / 3$ for $n=2$.

The skeletal filtration of the element

$$
x_{n}\left(V_{1}^{(b)}\right)=\left(\sum_{j=1}^{p-1} j^{-n} \lambda_{1}^{j} \otimes \lambda_{2}^{j} \otimes \cdots \otimes \lambda_{b}^{\prime}\right) / p^{1+v_{p}(n)}
$$

in $\operatorname{Ad}_{2 n-1}\left(B(\mathbb{Z} / p)^{b}\right)$ increases with $b$; for example

$$
\operatorname{SF}\left(x_{n}\left(V_{1}^{(b)}\right)\right)=2 \cdot b(p-1) \quad\left(n \equiv 0(p-1), v_{p}(n)=0, n \neq b(p-1)\right) .
$$

So to cover the dimension range left open by (4.4) for $b \geq p$ requires more sophisticated arguments than the simple one used above.
(d) To treat a non-abelian example, we consider the extra special $p$-group

$$
\begin{aligned}
Q & =(\mathbb{Z} / p \times \mathbb{Z} / p) \rtimes \mathbb{Z} / p=\left\{A, B, C \mid A^{p}=B^{p}=C^{p}\right. \\
& =[A, C]=[B, C]=1,[B, A]=C\} .
\end{aligned}
$$

Since $Q$ has $H^{\mathrm{ev}}(B Q ; \mathbb{Z})$ generated by Chern classes there is no problem with (2.15), see (4.5). We may proceed exactly as in the case $G=\mathbb{Z} / p \times \mathbb{Z} / p$. The skeletal filtration in $\operatorname{Ad}_{2 n-1}(B Q)=\bigoplus_{i=1}^{p+2} \mathbb{Z} / p^{1+v_{p}(n)}$ is bounded by $2(p-1)(3+$ $v_{p}(n)$ ). Therefore $\operatorname{Ad}_{2 n-1}(B Q)=\operatorname{im}\left(h_{A}\right)$ if $n>3 p$ by (4.2). If $n \leq 3 p$ we use the fact that $h_{A}: \pi_{2 n-1}^{s}(B Q) \rightarrow A_{2 n-1}(B Q)$ is onto for $n \leq(p-1) p$. Hence if $p \geq 5$ all dimensions are covered and we have

PROPOSITION 4.13. Let $p \geq 5$ be a prime and $Q=(\mathbb{Z} / p \times \mathbb{Z} / p) \rtimes \mathbb{Z} / p$. Then

$$
\operatorname{im}\left(h_{K}: \pi_{2 n-1}^{s}(B Q) \rightarrow K_{1}(B Q)\right) \cong \begin{cases}\operatorname{Ad}_{2 n-1}(B Q) & n>3 p \\ d\left(A_{2 n-1}(B Q)\right) & n \leqslant 3 p\end{cases}
$$

Remark 4.14. Theorem 4.4 is also true at $p=2$. Only the technical details are more involved. The Hurewicz map $h_{K}$ for complex $K$-theory factors through the KO-Hurewicz map $h_{\text {KO }}: \pi_{2 n-1}^{s}(B G)_{(2)} \rightarrow \mathrm{KO}_{2 n-1}(B G)_{(2)}$. Since $h_{\text {KO }}$ determines $h_{K}$ we consider $h_{\text {KO }}$. Then the 2-primary version of (4.4) is

Theorem 4.15. Let $G$ be a finite group. Then there exists $n_{0}(G)$ such that for $n \geq n_{0}(G)$ the image of the Hurewicz map

$$
h_{\mathrm{KO}}: \pi_{2 n-1}^{s}(B G)_{(2)} \rightarrow \mathrm{KO}_{2 n-1}(B G)_{(2)}
$$

is the subgroup $\operatorname{ker}\left(\psi^{3}-1\right)$.

We indicate only the main changes in the proof: Denote by $\mathrm{Ad}_{*}$ the fibre theory belonging to $\psi^{3}-1: \mathrm{KO}_{*}()_{(2)} \rightarrow \mathrm{KO}_{*}()_{(2)}$ and by $A_{*}$ the homology theory fitting into the exact sequence

$$
\rightarrow A_{i}(X) \rightarrow \mathrm{ko}_{i}(X)_{(2)} \xrightarrow{\psi^{3}-1} \operatorname{kspin}_{i}(X)_{(2)} \rightarrow A_{i-1}(X) \rightarrow
$$

where $\mathrm{ko}_{*}$ is $(-1)$-connected KO -theory and $\mathrm{kspin}_{*}$ its 2-connected cover. There is a $J$-map $j_{A}: A^{0}(X) \rightarrow \pi_{s}^{0}(X)_{(2)}$ such that the composition of $j_{A}$ with the Hurewicz map $\pi_{s}^{0}(X)_{(2)} \rightarrow A^{0}(X)$ is a bijection. If $X$ is simply connected, then $A^{0}(X)=$ $\operatorname{Ad}^{0}(X)$ (e.g. see [4]). Hence we have a statement corresponding to (4.2) for $p=2$ : If the skeletal filtration of $x \in \operatorname{Ad}_{2 n-1}(X)$ is small enough it will be in $\operatorname{im}\left(h_{A}\right)$.

Next one has to compute $\mathrm{KO}_{*}(B G)_{(2)}$. This may be done as in the complex case. One finds that $\mathrm{KO}_{*}(B G)_{(2)}$ consists of finitely many summands $\mathbb{Q} / \mathbb{Z}_{(2)}$ and $\mathbb{Z} / 2 \mathbb{Z}$ depending on the congruence class of $n \bmod 4$.

Elements of order 2 in $\operatorname{ker}\left(\psi^{3}-1\right)$ not divisible by 2 are most easily handled using Adams periodicity operators, e.g. see [4]. If $x \in \operatorname{ker}\left(\psi^{3}-1\right)$ is divisible by 2 then $y:=c(x / 2) \in \mathrm{KU}_{2 n-1}(B G)$ is an element with $r(y)=x$ where $c: \mathrm{KO} \rightarrow \mathrm{KU}$ and $r: K U \rightarrow K O$ are the canonical maps. Since $2 \cdot y$ is in $\operatorname{ker}\left(\psi^{3}-1\right)$, the exponent of 2 in the order of $y$ is of the form $a+v_{2}(n)$. Arguing as for $p \neq 2$ we find that for $n$ large enough $y$ comes from $\mathrm{KU}_{2 n-1}\left(B G^{(2 m)}\right)$ and $\left(\psi^{3}-1\right)(y)$ from $\mathrm{KU}_{2 n-1}\left(B G^{(2 d)}\right)$ with $m$ sufficiently small and $d$ depending only on $G$. Then the same is true for $x=r(y)$. Using the statement analogous to (2.15) the proof is finished as in the odd primary case.

## §5. $\operatorname{Im}\left(h_{K}\right)$ for cyclic groups in low dimensions

Let $C$ be the cyclic group of order $p^{c}, p \neq 2$. For the image of $h_{K}: \pi_{2 n-1}^{s}(B C) \rightarrow K_{1}(B C)$ there are two ranges for the values of $n$ and $c$ where we can find some sort of stability. The case of $c$ fixed and $n$ large is the one discussed above. The other extreme case is where $c$ is large and $n$ is fixed. In this case $B \mathbb{Z} / p^{c}$ approximates the complex projective space $P_{x} \mathbb{C}$. For the rest of this section we fix the notation $\xi=H^{p^{c}}$ where $H$ is the universal line bundle over $P_{x} \mathbb{C}$. Then the sphere bundle $S(\xi)$ is a model for $B \mathbb{Z} / p^{c}$ and the cofibre sequence

$$
\begin{equation*}
\rightarrow S(\xi)^{+} \xrightarrow{\pi} P_{x} \mathbb{C}^{+} \xrightarrow{j} P_{x} \mathbb{C}^{\xi} \xrightarrow{\delta} \Sigma S(\xi)^{+} \rightarrow \tag{5.1}
\end{equation*}
$$

relates $B \mathbb{Z} / p^{c}$ to $P_{x} \mathbb{C}$.

We recall the following facts about $A_{*}\left(P_{\infty} \mathbb{C}\right)$ from [13]: $A_{2 n}\left(P_{\infty} \mathbb{C}\right)=$ $\mathrm{Ad}_{2 n}\left(P_{\infty} \mathbb{C}\right)=\mathbb{Z}_{(p)}$ is generated by $b_{1}^{n} \in K_{0}\left(P_{\infty} \mathbb{C}\right)_{(p)}$ where $\left\{b_{j} \mid j \geq 1\right\}$ is the usual basis of $K_{0}\left(P_{\infty} \mathbb{C}\right)$ dual to the powers of $(H-1)$ and $b_{1}^{n}$ is the $n$-th power of $b_{1}$ with respect to the Pontrajagin product. The index of the canonical map $T: \mathrm{A}_{2 n}\left(P_{\infty} \mathbb{C}\right) \rightarrow H_{2 n}\left(P_{\infty} \mathbb{C}\right)_{(p)}$ is the $p$-part of $n!$. Write $n=t(p-1)+s$ with $0<s \leq(p-1)$ and let

$$
m=\sum_{i=1}^{t}\left(1+v_{p}(i)\right)-v_{p}(n!), \quad r=\left[\log \left(\frac{n+1}{s+1}\right) / \log (p)\right] .
$$

Then $A_{2 n-1}\left(P_{\infty} \mathbb{C}\right)$ is a group of order $p^{m}$ with $r$ cyclic summands. The kernel of the Bockstein map $\beta: A_{2 n}\left(P_{\infty} \mathbb{C} ; \mathbb{Q} / \mathbb{Z}\right) \rightarrow A_{2 n-1}\left(P_{\infty} \mathbb{C}\right)$ is given by the multiples of $b_{1}^{n}$.

The long exact sequence in $A$-theory induced by (5.1) reduces to a six term sequence

$$
\begin{align*}
& 0 \rightarrow A_{2 n}\left(P_{\infty} \mathbb{C}^{+}\right) \xrightarrow{j_{*}} A_{2 n}\left(P_{\infty} \mathbb{C}^{\xi}\right) \xrightarrow{\delta} A_{2 n-1}\left(B C^{+}\right) \xrightarrow{\pi_{*}} \\
& A_{2 n-1}\left(P_{\infty} \mathbb{C}^{+}\right) \xrightarrow{j_{*}} A_{2 n-1}\left(P_{\infty} \mathbb{C}^{\xi}\right) \xrightarrow{\delta} A_{2 n-2}\left(B C^{+}\right) \rightarrow 0 . \tag{5.2}
\end{align*}
$$

The description of $\mathrm{Ad}_{*}(B C)$ was given in (3.10) and the relation between $\mathrm{Ad}_{*}(B C)$ and $A_{*}(B C)$ is as follows. First of all, the exact sequence of $\left(B C^{(2 n)}, B C^{(2 n-1)}\right.$ ) shows

$$
A_{2 n-1}(B C)=\operatorname{Ad}_{2 n-1}\left(B C^{(2 n)}\right) .
$$

Since $B C, B C / B C^{(2 m)}$ and $B C^{(2 m)}$ have only non-zero homology in odd degrees, we find $K_{0}(B C)=0, K_{0}\left(B C / B C^{(2 m)}\right)=0$ and $K_{0}\left(B C^{(2 m)}\right)=0$. This implies that the maps $i_{*}: K_{1}\left(B C^{(2 m)}\right) \rightarrow K_{1}(B C), \quad D: \operatorname{Ad}_{2 n-1}(B C) \rightarrow K_{1}(B C)$ and $\quad D: \operatorname{Ad}_{2 n-1}\left(B C^{(2 m)}\right) \rightarrow K_{1}\left(B C^{(2 m)}\right) \quad$ are all injective. Therefore $i_{*}: \operatorname{Ad}_{2 n-1}\left(B C^{(2 n)}\right) \rightarrow \operatorname{Ad}_{2 n-1}(B C)$ and thus $d: A_{2 n-1}(B C) \rightarrow \operatorname{Ad}_{2 n-1}(B C)$ is injective. We shall describe elements in $A_{2 n-1}(B C)$ by their images in $\operatorname{Ad}_{2 n-1}(B C)$.

The first step in an investigation of (5.2) is the determination of $\operatorname{ker}\left(\pi_{*}\right)$.

LEMMA 5.3. $\operatorname{ker}\left(\pi_{*}\right) \cong \mathbb{Z} / p^{c+v_{p}(n)} \subset A_{2 n-1}(B C)$ is generated by

$$
z=x_{n}\left(v_{0}\right)+p^{n-1} x_{n}\left(v_{1}\right)+p^{2 n-2} x_{n}\left(v_{2}\right)+\cdots
$$

Proof. The commutative diagram

shows that $\operatorname{ker}\left(\pi_{*}: A_{2 n-1}(B C) \rightarrow A_{2 n-1}\left(P_{\infty} \mathbb{C}\right)\right)$ in contained in $\operatorname{ker}(\beta)=$ $\mathbb{Q} / \mathbb{Z}_{(p)} \cdot b_{1}^{n}$. The equation

$$
D\left(\pi_{*}\left(\sum_{i=0}^{c-1} x_{n}\left(v_{i}\right) \cdot p^{i(n-1)}\right)\right)=\frac{1}{p^{c+v_{p}(n)}} \cdot b_{1}^{n}
$$

is proved by evaluating $H^{k}-1 \in K^{0}\left(P_{x} \mathbb{C}\right), k \geq 1$, on both sides.
To see that $\operatorname{ker}\left(\pi_{*}\right)$ is always in $\operatorname{im}\left(h_{K}\right)$ we use the transfer map $t: A_{2 n-2}\left(P_{x} \mathbb{C}^{+}\right) \rightarrow A_{2 n-1}\left(B C^{+}\right)$. Denote by $\sigma \in \pi_{2}^{s}\left(P_{x} \mathbb{C}^{+}\right)$a generator with $h_{K}(\sigma)=b_{1}$. Then $\sigma^{n-1}$ generates $\pi_{2 n-2}^{s}\left(P_{x} \mathbb{C}^{+}\right) /$tor and $h_{A}\left(\sigma^{n-1}\right)$ generates $A_{2 n-2}\left(P_{x} \mathrm{C}^{+}\right)$.

LEMMA 5.4.

$$
h_{A}\left(t\left(\sigma^{n-1}\right)\right)=z=\sum_{i \geq 0} x_{n}\left(v_{i}\right) \cdot p^{i(n-1)} \text { in } \quad A_{2 n-1}(B C)
$$

Proof. We prove here only $h_{A} t\left(\sigma^{n-1}\right)=\lambda \cdot z$ with $\lambda \not \equiv 0(p)$.
Since $\pi_{*}{ }^{\circ} t=0$ we have im $(t) \subset \operatorname{ker}\left(\pi_{*}\right)$, so it is enough to compute the order of $\operatorname{im}(t)$. For this we use that the transfer map $t$ appears as boundary map in the cofibre sequence

$$
\rightarrow S(\xi)^{-\xi} \rightarrow P_{m} \mathbb{C}^{-\xi} \xrightarrow{i} P_{m} \mathbb{C}^{+} \xrightarrow{t} \Sigma S(\xi)^{-\xi} \rightarrow .
$$

Hence the order of im $(t)$ is given by the degree of the map

$$
j_{*}: A_{2 n-2}\left(P_{m} \mathbb{C}^{-\xi}\right) \rightarrow A_{2 n-2}\left(P_{m} \mathbb{C}^{+}\right), \quad m>n
$$

Claim. The index of $T: A_{2 n-2}\left(P_{m} \mathbb{C}^{-\xi}\right) \rightarrow H_{2 n-2}\left(P_{m} \mathbb{C}^{-\xi} ; \mathbb{Z}_{(p)}\right)$ is the $p$-part of
$n$ ! (independently of $c$, except for $p=2, c=1$ ). Then by comparing the degree of $j_{*}$ in $A$-theory with the degree of $j_{*}$ in homology gives: $\operatorname{deg}\left(j_{*}\right)=n \cdot p^{c}$ in $A$-theory. This shows im $(t)=\operatorname{ker}\left(\pi_{*}\right)$ in $A_{2 n-1}(B C)$ since both subgroups have the same order.

To prove the claim let $U_{K}(E)$ be the standard Thom class of a complex vector bundle $E$ in $K$-theory with the conventions ch $\left(U_{K}(E)\right)=\operatorname{Todd}(E) \cup U_{H}(E)$ and $\operatorname{Todd}(L)=\left(\exp \left(c_{1}(L)\right)-1\right) / c_{1}(L)$ for a line bundle $L$. Let $\operatorname{Bh}(E)=$ $\operatorname{ch}^{-1}(\operatorname{Todd}(E)) \in K^{0}\left(X^{+} ; \mathbb{Q}\right)$ and $\phi_{K}: K_{*}\left(X^{+}\right) \rightarrow K_{*}\left(X^{E}\right)$ be the Thom isomorphism associated with $U_{K}(E)$. It is an easy exercise to show that $w=$ $\phi_{K}^{-1}\left(b_{1}^{n} \cap \mathrm{Bh}(-\xi)\right) \in \mathrm{K}_{2 n-2}\left(\mathrm{P}_{\mathrm{n}} \mathbb{C}^{-\xi} ; \mathbb{Q}\right)$ is a $p$-integral class which is not divisible by any positive power of $p$. Since the Chern character of this class has only components in $H_{2 n-2}\left(P_{n} \mathbb{C}^{-\xi} ; \mathbb{Q}\right)$ it must be in $\operatorname{ker}\left(\psi_{2 n-2}^{l}-1\right)$. Now $\operatorname{ker}\left(\psi_{2 n-2}^{l}-1\right)$ $=\operatorname{Ad}_{2 n-2}\left(P_{n} \mathbb{C}^{-\xi}\right)=A_{2 n-2}\left(P_{n} \mathbb{C}^{-\xi}\right)$ is a direct summand in $\left.K_{2 n-2}\left(P_{n} \mathbb{C}^{-\xi}\right)_{(p)}\right)$. Hence $w$ is a generator of $\operatorname{ker}\left(\psi_{2 n-2}^{l}-1\right)$. It's image in $H_{2 n-2}\left(P_{n} \mathbb{C}^{-\xi} ; \mathbb{Z}_{(p)}\right) \cong$ $H_{2 n-2}\left(P_{n} \mathbb{C} ; \mathbb{Z}_{(p)}\right)$ is easily seen to be $n!$ times a generator.

Remarks. (i) A more direct computation of $t: A_{2 n-2}\left(P_{x} \mathbb{C}^{+}\right) \rightarrow A_{2 n-1}\left(B C^{+}\right)$ may be given as follows. It is proved in [12] that the composition

$$
K_{0}\left(P_{x} \mathbb{C}\right) \xrightarrow{\iota} K_{1}(B C) \stackrel{\beta}{\approx} K_{0}(B C ; \mathbb{Q} / \mathbb{Z}) \xrightarrow{\pi_{*}} K_{0}\left(P_{x} \mathbb{C} ; \mathbb{Q} / \mathbb{Z}\right)
$$

is given by $y \rightarrow y \cap e(\xi)^{-1}$ where $e(\xi)=H^{p^{\prime}}-1$ is the $K$-theory Euler class of $\xi$. (For $y \in K_{0}\left(P_{x} \mathbb{C}\right)$, the cap product $y \cap e(\xi)^{-1}$ in $K_{0}\left(P_{x} \mathbb{C} ; \mathbb{Q}\right)$ makes sense, since $y=y^{\prime} \cap(H-1)$ and $e(\xi) /(H-1)$ is invertible in $K^{0}\left(P_{x} \mathbb{C} ; \mathbb{Q}\right)$ ). The equation $h_{A}\left(t\left(\sigma^{n-1}\right)\right)=z$ then follows by evaluating $H^{k}-1, k \geq 1$, on both sides. This resolves the factor $\lambda$.
(ii) For $p \neq 2$ (5.3) and (5.4) reprove:

$$
\operatorname{im}\left(h_{K}: \pi_{2 n-1}^{s}(B \mathbb{Z} / p) \rightarrow K_{1}(B / \mathbb{Z} / p)\right)=\mathbb{Z} / p^{1+v_{p}(n)} \text { is generated by } h_{K}\left(t\left(\sigma^{n-1}\right)\right) .
$$

The sequence (5.2) can now be written as

$$
\begin{align*}
0 \rightarrow \mathbb{Z} / p^{c+v_{p}(n)} \rightarrow A_{2 n-1}\left(B C^{+}\right) \xrightarrow{\pi_{*}} & A_{2 n-1}\left(P_{x} \mathbb{C}^{+}\right) \\
& \xrightarrow{j .} A_{2 n-1}\left(P_{x} \mathbb{C}^{\xi}\right) \rightarrow A_{2 n-2}\left(B C^{+}\right) \rightarrow 0 . \tag{5.5}
\end{align*}
$$

Fix now $n$. If $c$ is large enough, the map $j_{*}$ must be the zero map in $A_{*}$-theory as well as in stable homotopy. This may be seen as follows. We can write $j$ as a
composition of maps $P_{\infty} \mathbb{C}^{H^{p^{\prime}}} \rightarrow P_{\infty} \mathbb{C}^{H^{p^{+1}}}$ of Adams filtration $>0$. By increasing $c$ we can increase the Adams filtration of $j$. If the Adams filtration of $j$ is large enough, $j_{*}$ is the zero map. Or: for $c$ large the bundle $\xi \rightarrow P_{n} \mathbb{C}$ is stably fibre homotopy trivial at $(p)$. So $\xi$ is orientable for $\pi_{s}^{*}()_{(p)}$ and $A^{*}$ and (5.5) becomes the usual Gysin sequence of the line bundle $\xi$. Then $j_{*}$ is given by the cap-product with the Euler class of $\xi$. If $c$ is large enough $j_{*}$ must be zero since $e(\xi)$ is divisible by a large power of $p$. We have proved

PROPOSITION 5.6. For $n$ fixed clarge enough we have

$$
A_{2 n-1}\left(B \mathbb{Z} / p^{c}\right) \cong A_{2 n-1}\left(P_{\infty} \mathbb{C}\right) \oplus \mathbb{Z} / p^{c+v_{p}(n)}
$$

and $\operatorname{cok}\left(h_{A}\right)$ in $A_{2 n-1}\left(B \mathbb{Z} / p^{c}\right)$ is isomorphic to $\operatorname{cok}\left(h_{A}\right)$ in $A_{2 n-1}\left(P_{x} \mathbb{C}\right)$.
Notice that this means that $A_{2 n-1}\left(B \mathbb{Z} / p^{c}\right) / \operatorname{im}(\delta)$ is independent of $c$ for $c$ large.

Some elements in $\operatorname{cok}\left(h_{A}: \pi_{2 n-1}^{s}\left(P_{x} \mathbb{C}\right) \rightarrow A_{2 n-1}\left(P_{x} \mathbb{C}\right)\right)$ are determined for example in [13]. Except for very low values of $n, h_{A}$ is never onto and $\operatorname{cok}\left(h_{A}\right)$ becomes arbitrary large for increasing $n$, see [13] or [14].

The lowest dimensional example where $h_{A}: \pi_{2 n-1}^{s}\left(B \mathbb{Z} / p^{c}\right) \rightarrow A_{2 n-1}\left(B \mathbb{Z} / p^{c}\right)$ is not onto is the following

EXAMPLE 5.7. Let $n=p^{2}-1, p \neq 2$, then

$$
\begin{aligned}
& A_{2 n-1}\left(P_{\infty} \mathbb{C}\right) \cong \mathbb{Z} / p^{2} \text { generated by } \pi_{*}\left(x_{n}\left(v_{1}\right)\right), \quad \operatorname{im}\left(h_{A}\right) \cong \mathbb{Z} / p \\
& \operatorname{Ad}_{2 n-1}\left(B \mathbb{Z} / p^{3}\right)=\mathbb{Z} / p^{3} \oplus \mathbb{Z} / p^{2} \oplus \mathbb{Z} / p \\
& A_{2 n-1}\left(B \mathbb{Z} / p^{3}\right)=\mathbb{Z} / p^{3} \oplus \mathbb{Z} / p^{2} \\
& \operatorname{im}\left(h_{A}\right)=\mathbb{Z} / p^{3} \oplus \mathbb{Z} / p \text { generated by } x_{n}\left(v_{0}\right) \text { and } p \cdot x_{n}\left(v_{1}\right)
\end{aligned}
$$

If $\pi_{*}\left(x_{n}\left(v_{1}\right)\right)$ is not stably spherical, then the same must be true for $x_{n}\left(v_{1}\right)$. To show that $\pi_{*}\left(x_{1}\left(v_{1}\right)\right)$ is not stably spherical is particularly easy. The following method usually detects few elements in $\operatorname{cok}\left(h_{A}\right)$ but works in this case.

Let $\mathrm{ch}_{m}$ denote the $m$-th term of the Chern character, $q=2 p-2$ and $k$ connected $p$-local $K$-theory. Then it is well known that $p^{m} \cdot \mathrm{ch}_{q m}$ is integral at $p$ and gives a class in $H^{q \cdot m}\left(k ; \mathbf{Z}_{(p)}\right)$. This class defines natural transformations

$$
Q_{m}: k_{i}(X) \rightarrow H_{i-m q}\left(X ; \mathbb{Z}_{(p)}\right) \quad \text { and } \quad Q_{m}: k_{i}(X ; \mathbb{Q} / \mathbb{Z}) \rightarrow H_{i-m q}\left(X ; \mathbb{Q} / \mathbb{Z}_{(p)}\right)
$$

The composition

$$
A_{2 n}(X ; \mathbb{Q} / \mathbb{Z}) \xrightarrow{D} k_{2 n}(X ; \mathbb{Q} / \mathbb{Z}) \xrightarrow{Q_{m}} H_{2 n-q m}\left(X ; \mathbb{Q} / \mathbb{Z}_{(p)}\right)
$$

clearly vanishes on stably spherical classes $(m>0)$. For $m=p$ it can be used to show $\pi_{*}\left(x_{n}\left(v_{1}\right)\right) \notin \operatorname{im}\left(h_{A}\right), n=p^{2}-1$. We omit the easy calculation; see e.g. [14].

Notice also that this case is already stable in the sense of (5.6). For $n=p^{2}-1$ and all $c \geq 3$ we have $A_{2 n-1}\left(B \mathbb{Z} / p^{c}\right)=\mathbb{Z} / p^{c} \oplus \mathbb{Z} / p^{2}$ and im $\left(h_{A}\right)=\mathbb{Z} / p^{c} \oplus \mathbb{Z} / p$ by the same argument as above. For $c=1$ we have $\operatorname{Ad}_{2 n-1}(B \mathbb{Z} / p)=A_{2 n-\mathrm{i}}(B \mathbb{Z} / p)$ for all $n \geq 2$ and $h_{A}$ is onto by (5.4). The case $c=2$ is also exceptional. It turns out that the bound $n_{0}\left(\mathbb{Z} / p^{2}\right)$ beyond which $h_{A}$ is onto by (4.4) is small enough to allow a direct computation for the rest of the dimensions.

## PROPOSITION 5.8. Let p be an odd prime, then

$$
h_{A}: \pi_{2 n-1}^{s}\left(B \mathbb{Z} / p^{2}\right) \rightarrow A_{2 n-1}\left(B \mathbb{Z} / p^{2}\right) \text { is onto. }
$$

Proof. We only sketch the argument. Only the elements $x_{n}\left(v_{1}\right)$ of order $p^{1+v_{p}(n)}$ have to be considered. In the first step one works out that the skeletal filtration of $x_{n}\left(v_{1}\right)$ is less than $2(p-1) p\left(2+v_{p}(n)\right)$ by (2.14). Except for $p=3$ this implies: if $v_{p}(n) \geq 3$ then $x_{n}\left(v_{1}\right) \in \operatorname{im}\left(h_{A}\right)$ for all $n$ and if $v_{p}(n) \leq 2$ then $x_{n}\left(v_{1}\right) \in \operatorname{im}\left(h_{A}\right)$ if $n>3 p^{2}$.

The remaining cases are checked by hand. Only for $n \geq(p-1) p$ there is something to show; for smaller values of $n h_{A}: \pi_{2 n-1}^{s}(X) \rightarrow A_{2 n-1}(X)$ is bijective since $\operatorname{cok}(J)=0$. Next one works out which multiple $p^{s} \cdot x_{n}\left(v_{1}\right)$ is in $A_{2 n-1}\left(B \mathbb{Z} / p^{2}\right)$. The elements in $\pi_{2 n-1}^{s}\left(B \mathbb{Z} / p^{2}\right)$ needed to generate im $\left(h_{A}\right)$ are first of all constructed in $\pi_{2 n-1}^{s}\left(P_{\infty} \mathbb{C}\right)$ using the transfer map $t: \pi_{2 n-2}^{s}\left(P_{\infty} \mathbb{C}_{\wedge} P_{\infty} \mathbb{C}\right) \rightarrow$ $\pi_{2 n-1}^{s}\left(P_{\infty} \mathbb{C}\right)$ (see e.g. [13], [14]) and then by considering the exact sequence in stable homotopy induced by (5.1). To see that the elements in question indeed come from $\pi_{2 n-1}^{s}\left(B \mathbb{Z} / p^{2}\right)$ one shows that they map to zero in $\pi_{2 n-1}^{s}\left(P_{\infty} \mathbb{C}^{H^{p^{2}}}\right)$. This is done by proving that in those dimension $h_{A}$ is injective, allowing to do the calculation in $A$-theory. Adams periodicity (e.g. see [4]) reduces the number of cases where one has to construct an element mapping to

$$
x_{n}\left(v_{1}\right) \text { or } p \cdot x_{1}\left(v_{1}\right)
$$

EXAMPLE 5.9. Let $p=3$. $A_{2 n-1}(B \mathbb{Z} / 9)$ is cyclic for $n=1,2,3,4,6$, the index of $A_{2 n-1}(B \mathbb{Z} / 9)$ in $\mathrm{Ad}_{2 n-1}(B \mathbb{Z} / 9)$ is 3 for $n=12,18$ and 9 for $n=9$. In the other dimensions we have $A_{2 n-1}(B \mathbb{Z} / 9)=\operatorname{Ad}_{2 n-1}(B \mathbb{Z} / 9)$.
