Simo hirticornis (Herbst, 1795) and *S. variegatus* (Boheman, 1843)
in Switzerland — on their distribution and a reliable identification
(Coleoptera, Curculionidae)

CHRISTOPH GERMANN¹ & MARCO MORETTI²

¹ Natur-Museum Luzern, Kasernenplatz 6, CH-6003 Luzern and Naturhistorisches Museum der Burgergemeinde Bern, Bernastrasse 15, CH-3005 Bern, Email: christoph.germann@lu.ch

² Swiss Federal Research Institute WSL, Insubric Ecosystems Research Group, Via Belsoggiorno 22, CH-6500 Bellinzona

Distribution patterns of *Simo hirticornis* and *S. variegatus* are presented for the first time for Switzerland based on an extensive data set of 1393 specimens, since the species state of *S. variegatus* was revised in 1995. New insights into their ecological requirements are presented. An additional morphological character to distinguish the two sibling species in Switzerland is further provided.

Keywords: Curculionoidea, Entiminae, morphology, ecology, sibling species, determination

INTRODUCTION

The genus *Simo* Dejean, 1821 was recently revised by Pierotti & Bellò (2006). Presently, *Simo* comprises four Mediterranean species, two of them — *Simo hirticornis* (Herbst, 1795) and *S. variegatus* (Boheman, 1843) — also occur in Central Europe. Although already described in 1843, *S. variegatus* was considered as a valid species only after Palm (1995), who showed for the first time relevant characters that allowed a reliable differentiation from the closely related *S. hirticornis*. Knu-telski *et al.* (1997) provided an overview of the distribution of the two species in Europe. Behne (1998) added *S. variegatus* in a supplement to the most often used identification key «Die Käfer Mitteleuropas». Just recently Heijerman (2002) deleted *S. hirticornis* from the species list of Denmark, Stejskal (2005) recorded *S. variegatus* for the Czech Republic and Braunert (2009) listed both species for Luxembourg. In synthesis, the overall distribution of the two species is as follows (after literature cited): *Simo hirticornis* (Locus typicus: Germany): France including Corse, Switzerland, north-western Greece, Netherlands, Germany, South of Sweden, Luxembourg, Poland, Czech Republic, Slovakia, Spain, Austria, Serbia, Croatia, and Italy. *Simo variegatus* (Locus typicus: Switzerland, Geneva): France (Corse doubtful), Switzerland, Denmark, Germany, Poland, Slovakia, Czech Republic, Hungary, Luxembourg, Austria, Serbia, and Italy.

The distribution of *S. variegatus* was little known in Switzerland so far, because of the late recognition of its species state. This lack of data was subsequently made up through an extensive data survey based on specimens from Museum collections, private collections, and material from scientific investigations of the Swiss Federal Research Institute (WSL hereafter) in the run up of a checklist of the Swiss weevils (Germann 2010). Furthermore, a new character for the reliable differentiation of the two species was found based on the specimens examined, which is presented and illustrated in the following.

MATERIAL AND METHODS

From the following collections specimens were examined (in alphabetical order):

BNM	Bündner Naturmuseum, Chur
cCG	collection Christoph Germain, Thun
cMG	collection Michael Geiser, Basel
cRG	collection Roman Graf, Luzern
cYC	collection Yannick Chittaro, Conthey
ETHZ	Eidgenössische Technische Hochschule, Zürich
IBUN	Institut de Biologie de l'Université de Neuchâtel
MHNF	Muséum d'Histoire Naturelle de Fribourg
MHNG	Muséum d'Histoire Naturelle de Genève
NMBA	Naturhistorisches Museum, Basel
NMBE	Naturhistorisches Museum der Burgergemeinde, Bern
NMLU	Natur-Museum, Luzern

Additional specimens were sampled by the WSL Bellinzona and Birmensdorf during several biodiversity surveys and specific studies in various regions of the canton Ticino (Brissago 696.850 / 107.600, Ronco s. Ascona 698.350 / 110.600, Locarno 703.300 / 114.700, Minusio 705.350 / 115.600, Gordola 709.900 / 116.600, Tenero-Contra 708.500 / 117.000, Pura 710.900 / 093.600, S. Antonino 720.100 / 112.100, Bolle di Magadino 709.050 / 112.850), Graubünden (Soazza 736.800 / 135.400), and Valais (Leuk 616.300 / 131.200).

All specimens were sampled with standard methods (Duelli *et al.* 1999). Litter dwelling species were sampled using pitfall traps, which consisted of 1 funnel recessed into the soil (opening diameter 13 cm) filled with a 2 % formalin solution, and protected from the rain by transparent roofs. Traps were emptied every week, mostly from April to September. Details about the projects by the WSL are available by the second author.

The first author identified 1393 *Simo* specimens in total. The identification was based on ectoskeletal characters, and the spermathecae that were obligatorily examined. The identification keys of Palm (1995), Knutelski *et al.* (1997), Behne (1998), and Pierotti & Bellò (2006) were used. The pictures of the setae on the elytral disc were taken with a digital camera (3 mega pixel, JVC) through a binocular (Leica MZ16). The images were modified with the program Auto-Montage (Synoptics) for best results in depth of sharpness, and then reworked using Adobe Photoshop version 10.0.1 (Adobe Systems Incorporated).

RESULTS

Geographical distribution

We examined 156 specimens of *Simo variegatus*, and 271 specimens of *S. hirticornis* from different collections in Switzerland (Appendix 1), as well as 738 specimens of *S. hirticornis* from central to southern canton Ticino, and 228 specimens of *S. variegatus* from the Valais, caught during biodiversity surveys of the WSL. All finding sites of the two species are presented (Figs 1 and 2). *Simo variegatus* was recorded in 12 cantons (Aargau, Basel, Bern, Freiburg, Genève, Graubün-

Fig. 1. Finding sites of *Simo hirticornis* (Herbst, 1795) in Switzerland (copyright CSCF).

den, Neuchâtel, Schaffhausen, Solothurn, Ticino, Vaud, Valais), *S. hirticornis* in 8 cantons (Bern, Freiburg, Graubünden, Neuchâtel, St. Gallen, Ticino, Vaud, Valais).

Vertical distribution

Based on the collection data, 99 sites of the 156 specimens of *Simo variegatus* were located at a mean altitude of 709 ± 397 m a.s.l. (min. 270 – max. 2006 m), while 147 sites of the 271 specimens of *S. hirticornis* were located at a mean altitude of 963 ± 439 m a.s.l. (min. 200 – max. 2200 m).

Morphology and discrimination characters

The morphological characters commonly used to identify the two species (see point 1 to 5 below) show some variability, as illustrated in the identification keys of Palm (1995), Knutelski *et al.* (1997), Behne (1998), and Pierotti & Bellò (2006), the latter with extensive illustrations.

In our study we identified a new character of the elytral setae (see point 6 below), that hardly shows any variability among the 1393 *Simo* specimens considered, especially when the antennal groove is polluted (see point 2 below), as it was often observed.

1. Width of rostrum (in *variegatus* wider compared with the most narrow point of the rostrum of *hirticornis*).

2. Scales between the eye and the antennal groove (in *variegatus* with isolated scales, in *hirticornis* with dense, overlapping scales).

3. Spermatheca (in *variegatus* with a large and thin cornus; the basis broader than in *hirticornis*).

Fig. 2. Finding sites of *Simo variegatus* (Boheman, 1843) in Switzerland (copyright CSCF).

4. Antennal articles (*variegatus* last articles before club transverse, stronger than in *hirticornis*).
5. Propygidium (in *variegatus* apically rounded or spatuliform, in *hirticornis* pointed).
6. New character: Setae on elytral disc (Fig. 3A: in *variegatus* dark, weakly bowed, raised setae on the intervals; Fig. 3B: in *hirticornis* with bright, strongly bowed, adherent setae).

DISCUSSION

Distributional Patterns

The geographical distribution of the two *Simo* species in Switzerland based on the museum specimens shows an apparent lack of records from the Northern side of the Alps and from Central Switzerland, as well as an almost complete lack of *variegatus* from Graubünden (*variegatus*: 4; *hirticornis*: 47 specimens) and the canton of Ticino (*variegatus*: 1; *hirticornis*: 52 specimens). The first lack of records is strongly suspected to be due to undersampling, whereas in the second case, other explanations are needed and provided. In the canton of Ticino, *hirticornis* clearly dominates, which was confirmed by intensive sampling at nine localities (see Material and Methods) and 738 specimens in chestnut forests. If the silicate ground is an explanatory factor, this could not be shown unambiguously, as *Simo variegatus* was also recorded on silicate grounds. Of particular interest thereby are records from Valais, where the underlying ground (silicate or limestone) apparently does not seem to have an influence. However, a decisive factor might be the exposition towards South and/or the degree of xerothermal biotopes, where *variegatus* can be found

Fig. 3. A: *Simo variegatus* (Boheman, 1843): Switzerland, Valais: Chelin. — B: *Simo hirticornis* (Herbst, 1795): Italy, Piemonte: Gran Paradiso.

exclusively. This was shown impressively in a burnt forest area above Leuk, Valais (Moretti *et al.* 2010). Additionally, interesting insights into a transition-zone near Martisberg (Valais) were gained on an excursion in June 2008 where both *Simo* species were found in sympatry. The biotope consisted of an open *Picea abies* — *Pinus sylvestris* forest at 1300 m a.s.l., where xerotherm shrubs change into montane *Picea abies* forest.

A possible dependence of *variegatus* on an underlying limestone ground was suspected by Palm (1995) and Knutelski *et al.* (1997). However, already Stejskal (2005) did not confirm this hypothesis. Nevertheless, in the Jura Mountains (limestone) *hirticornis* was solely found in few exemplars, whereas *variegatus* seems to dominate.

As a conclusion, collection data (Appendix 1) and partly included data of biotopes of these finds (Germann, unpublished) in Switzerland show that *Simo hirticornis* lives in mixed forests, montane *Picea abies* forests (Northern side of the Alps), at forest edges, in gardens (Swiss Midlands) and in (chestnut-)deciduous forests (Southern Switzerland, Ticino), whereas *Simo variegatus* lives in southern exposed open *Pinus sylvestris* forests, partly mixed with xerotherm shrubs (Valais), *Quercus pubescens/petraea* forests (southern slopes of Jura Mountains) and in (garden-)hedges (Swiss Midlands).

Our study clearly shows that the vertical distributions of both *Simo* species in Switzerland is very broad and overlaps almost completely. However, *Simo hirticornis* was found on average at higher altitude than *variegatus*. This might be related to microclimatic preferences of the two species with *S. variegatus* preferring xerothermal biotopes and milder climate (Knutelski *et al.* 1997) compared to *hirticornis* whose distribution extends up to southern Scandinavia, whereas *variegatus* is absent there. Although our findings are overall consistent with the data known up to now, the broad overlap of the two species in their vertical distribution has not been shown so far.

Remarks on the biology of the two Simo species

For both species we present for the first time specimen rich data collections: *Simo hirticornis* in 738 specimens in canton Ticino, and *S. variegatus* in 228 specimens in the Valais above Leuk. Such contrasting biotopes, as chestnut forests in Ticino under Insubric climate conditions — mild and dry in winter, and rainy and hot in summer — or xerothermal slope with rocky steppe and conifers (*Pinus sylvestris*), and the continental climate (dry and winter-cold) in the Valais, are indeed colonised very specifically by each of the two species.

The sympatric occurrence of the two species — presently stated as a rare event after Knutelski *et al.* (1997) — was detected at various locations, namely in Bern (city of Bern), especially in the Valais (Bramois, Euseigne, Evolène, Martigny, Martisberg, Saas, St-Léonard, St-Maurice, Simplon), Ticino (Valle Verzasca) and Graubünden (Scuol, Tarasp). The sympatric occurrence of the two species in anthropogenically formed biotopes (e.g. botanical garden, city of Bern) might point out, that both species also spread out via ornamental shrubs and eventually, an original separation of biotopes might be blurred. In their foraging behaviour, both species are polyphagous on deciduous and coniferous trees and shrubs (Knutelski *et al.* 1997). In urban areas of Switzerland, both species were recorded on ornamental garden shrubs (*Cotoneaster* sp., *Prunus* spp.) as well as on herbaceous plants (*Primula* sp.) (Germann, pers. observations).

All specimens examined from Switzerland were females; both species show an exclusively parthenogenetic reproduction in a large part of the distribution area. Males of both species were only reported from Northern Italy (Piemonte) by Pierotti & Bellò (2006). Suomalainen (1954) found triploid and tetraploid specimens of *S. hirticornis* from Switzerland, however, without considering both taxa. A

re-examination of the specimens was unfortunately not possible, despite intensive investigations in the Finnish Museum of Natural History in Helsinki. The larvae of neither of the species has ever been described, nor is their larval development known. Nevertheless, as in other Entiminae, a predominantly ectophagous larval development on roots in the soil can be hypothesized.

Morphology

The determination of the two very similar species *Simo variegatus* and *S. hirticornis* is simplified with an additional reliable and conspicuous character; the setae on the elytra, especially on the elytral disc. This character is best visible if specimens are held in a lateral position (see Fig. 3). However, as this trait was only tested on the Swiss specimens available, we advocate for a further study the inclusion of more samples from various regions to verify its broader reliability. A combination of all characters is still the best guarantee for a confident discrimination of the two species.

ACKNOWLEDGEMENTS

We thank André Fasel (MHNF), Peter Herger and Denise Wyniger (NMLU), Charles Huber (NMBE), Giulio Cuccodoro and Bernhard Merz (MHNG), Franziska Schmid and Andreas Müller (ETHZ), Ulrich Schnepf and Marion Schmid (BNM), and Eva Sprecher (NMBA) for the loan of specimens. Martin Obrist, Beat Wermelinger, Peter Duelli, Peter Wirz, and Franco Fibbioli, who were involved in most of the WSL projects in Ticino and Valais. We are thankful to Matthias Borer (IBUN), Yannick Chittaro (Conthey), Michael Geiser (Basel), Roman Graf (Luzern), Werner Marggi (Thun), and Peter Sonderegger (Brugg) for providing specimens and for the possibility to use their data. We thank Simon Capt (CSCF, Centre Suisse de Cartographie de la Faune, Neuchâtel) for the maps of the finding sites. Olof Biström (Finnish Museum of Natural History of Helsinki) kindly tried to locate the *Simo* specimens of Suomalainen in the Museum collection, although without success, we are thankful for his investigations. For his comments on an earlier version of the manuscript we thank Helio Pierotti (Italy, Treviso).
